Ancient and Eternal Solutions

- We will discuss ancient or eternal solutions to geometric parabolic partial differential equations.
- These are special solutions which exist for all time

 $-\infty < t < T$ where $T \in (-\infty, +\infty]$.

- They appear as blow up limits near a singularity.
- Understanding ancient and eternal solutions often sheds new insight to the singularity analysis

In this talk we will address:

- the classification of ancient solutions to parabolic partial differential equations, with emphasis to geometric flows: Mean Curvature flow, Ricci flow and Yamabe flow.
- methods of constructing new ancient solutions from the gluing of two or more solitons (self-similar solutions).
- new techniques and future research directions.

- Definition: A solution u(·, t) to a parabolic equation is called ancient if it is defined for all time −∞ < t < T, T < +∞.
- Ancient solutions typically arise as blow up limits at a type I singularity.
- Definition: A solution u(·, t) to a parabolic equation is called eternal if it is defined for all −∞ < t < +∞.
- Eternal solutions as blow up limits at a type II singularity.

Solitons

- Solitons (self-similar solutions) are typical examples of ancient or eternal solutions and often models of singularities.
- Some typical examples of solitons to geometric PDE are:
- Spheres:

• Cylinders:

• Translating solitons:

∃ ► < ∃ ►</p>

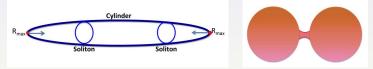

Panagiota Daskalopoulos Ancient Solu

Ancient Solutions to Geometric Flows

- A well known technique introduced by R. Hamilton (1995) has been widely used to characterize as solitons the eternal solutions to geometric flows which attain a space-time curvature maximum.
- Such solutions typically appear as *carefully chosen* blow up limits near type II singularities.
- Its proof relies on a clever combination of the strong maximum principle and Li-Yau type differentiable Harnack estimates.

Other Ancient and eternal solutions

- However, there exist other ancient or eternal solutions which are not solitons.
- These, often may be visualized as obtained from the gluing as $t \to -\infty$ of two or more solitons.

- Obtaining more information about such solutions, often leads to the better understanding of the singularities.
- Objective: How to construct such solutions and how to characterize them among all ancient or eternal solutions.

Goal: Characterize all ancient or eternal solutions to a geometric flow under natural geometric conditions:

- Being a soliton (self-similar solution)
- Satisfying an appropriate curvature bound as $t \to -\infty$:
 - i. Type I: global curvature bound after typical scaling.
 - ii. Type II: solutions which are not type I.
- Satisfying a non-collapsing condition.

The Semi-linear heat equation

• Consider next the semilinear heat equation

$$(\star_{SL})$$
 $u_t = \Delta u + u^p$ on $\mathbb{R}^n \times (0, T)$

in the subcritical range of exponents 1 .

- It provides a prototype for the blow up analysis of geometric flows.
- In particular in neckpinches of solutions to the Ricci flow and Mean Curvature flow.
- Also in the characterization of rescaled limits as t → -∞ of ancient solutions.

The rescaled semi-linear heat equation

• Self-similar scaling at a singularity at (a, T):

$$w(y,\tau) = (T-t)^{\frac{1}{p-1}} u(x,t), \ y = \frac{x-a}{\sqrt{T-t}}, \ \tau = -\log(T-t).$$

- Giga Kohn (1985): $||w(\tau)||_{L^{\infty}(\mathbb{R}^n)} \leq C, \ \tau > -\log T.$
- The rescaled solution satisfies the equation

$$(\star) \qquad w_ au = \Delta w - rac{1}{2} y \cdot
abla w - rac{w}{p-1} + w^p.$$

- Objective: To analyze the blow up behavior of u one needs to understand the long time behavior of w as τ → +∞.
- This is closely related to the classification of bounded eternal solutions of (*).

Eternal solutions of the semi-linear heat equation

• Problem: Provide the classification of bounded positive eternal solutions *w* of equation

(*)
$$w_{\tau} = \Delta w - \frac{1}{2}y \cdot \nabla w - \frac{w}{p-1} + w^{p}.$$

- Eternal means that $w(\cdot, \tau)$ is defined for $\tau \in (-\infty, +\infty)$.
- The only steady states of (*) are the constants:

$$w = 0$$
 or $w = \kappa$, with $\kappa := (p-1)^{-\frac{1}{(p-1)}}$.

- Theorem (Giga Kohn '87) $\lim_{\tau \to \pm \infty} w(\cdot, \tau) =$ steady state.
- Space independent eternal solutions : $\phi(\tau) = \kappa (1 + e^{\tau})^{-\frac{1}{(p-1)}}$.

Classification of Eternal solutions

• Theorem (Giga - Kohn '87 and Merle - Zaag '98) If w is bounded positive eternal solution of (\star) defined on $\mathbb{R}^n \times (-\infty, +\infty)$, then

$$w = 0$$
 or $w = \kappa$ or $w = \phi(\tau - \tau_0)$.

 Main difficulty (Merle - Zaag): Classify the orbits w(·, τ) that connect the two steady states:

$$\lim_{\tau \to -\infty} w(\cdot, \tau) = \kappa \quad \text{and} \quad \lim_{\tau \to +\infty} w(\cdot, \tau) = 0$$

• Elliptic analogues: In similar spirit as the well known results by Gidas-Ni-Nirenberg '79 and Berestycki-Nirenberg '91 for global solutions to the elliptic equation

$$\Delta u + u^{p} = 0, \qquad \text{on } \mathbb{R}^{n}.$$

Other Liouville type results related to equation (*_{sl}) by: P.
 Polacik, P. Quittner, T. Bartsch, P. Souplet, E. Yanagida among others.

Liouville type results for solutions to parabolic equations

- Although Liouville type results often appear with respect to elliptic equations, there are not many such results available in the parabolic setting.
- G. Koch, N. Nadirashvili, G. Seregin and V. Sverak (2009):
 (i) Liouville type result for ancient bounded solutions of the 2-dim Navier Stokes equations.

(ii) Also, similar result for bounded, axi-symmetric with no swirl solutions of the 3-dim Navier Stokes equations.

• The proof relies on a weak type variation of the strong maximum principle for weak solutions of

 $u_t + a(x, t) \cdot \nabla u - \Delta u = 0.$

• This result is applied on the vorticity $\omega := \operatorname{curl} u$.

Ancient Convex solutions to the CSF

• Let Γ_t be a family of closed curves which is an embedded solution to the Curve shortening flow, i.e. the embedding $F: \Gamma_t \to \mathbb{R}^2$ satisfies

$$\frac{\partial F}{\partial t} = -\kappa \, \nu$$

with κ the curvature of the curve and ν the outer normal.

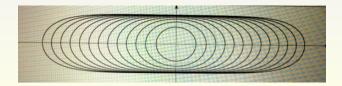

- Gage (1984); Gage and Hamilton (1996); Grayson (1987): the CSF shrinks Γ_t to a round point.
- Problem: Classify the ancient compact embedded solutions to the Curve shortening flow.

Ancient Convex solutions to the CSF

• The curvature κ of Γ_t evolves, in terms of its arc-length s, by

$$\kappa_t = \kappa_{ss} + \kappa^3.$$

- Examples of solutions in closed form:
 - **1** Type I: the contracting circles.
 - ② Type II: the Angenent ovals (paper clips). They are not solitons. As t → -∞ they may be visualized as two grim reaper solutions glued together.

The Classification of Ancient Convex solutions to the CSF

- Theorem (D., Hamilton, Sesum 2010) The only ancient convex solutions to the CSF are the contracting spheres or the Angenent ovals.
- Proof: It is based on:
 - i. two monotonicity formulas and
 - ii. the fact that at its singular time any solution becomes circular with very sharp rates of convergence.

Non-Convex ancient solutions

- Question: Do they exist non convex compact embedded solutions to the curve shortening flow ?
- Angenent (2011): Presents a YouTube video of an ancient solution to the CSF built out from one Yin-Yang spiral and one Grim Reaper.

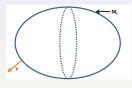

• S. Angenent: is currently working on a rigorous construction of these solutions.

The Mean curvature flow

(MCF)

 Let M_t, t ∈ (-∞, T) be a smooth ancient compact solution of the Mean curvature flow

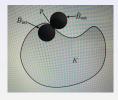

H(p, t) is the Mean curvature and ν a choice of unit normal.

 $\frac{\partial F}{\partial t} = -H\nu$

• Problem: Understand ancient compact solutions M_t of the Mean curvature flow.

Ancient non-collapsed solutions to MCF

• Weimin Sheng and Xu-Jia Wang; Ben Andrews: Introduced an α-noncollapsed condition.

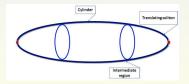

$$B = B_{\frac{\alpha}{H(p)}}$$

- Haslhofer & Kleiner (2013): Ancient compact + α -noncollapsed MCF solution \Rightarrow convex.
- convex compact + self-similar MCF solution \Rightarrow sphere.
- Ancient ovals: Any compact and α-noncollapsed solution to MCF which is not self-similar.
- Other ancient solutions to MCF: compact and collapsed.

Ancient MCF ovals

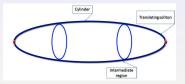

- Problem: Provide the classification of all Ancient ovals.
- B. White (2003): Existence of certain Ancient ovals with $O(k) \times O(l)$ symmetry. We call them White ancient ovals.
- Haslhofer & Hershkovits (2013): Give more details in the existence proof of the White Ancient ovals.
- Angenent (2012): establihes the formal matched asymptotics of all Ancient ovals as $t \to -\infty$.

• They are small perturbations of ellipsoids.

Unique asymptotics of Ancient MCF ovals

• S. Angenent, D., and N. Sesum (2015): All ancient ovals with $O(1) \times O(n)$ symmetry have unique asymptotics as $t \to -\infty$, and satisfy Angenent's precise matched asymptotics:

• Geometric properties $t \to -\infty$: type II ancient solutions

$$\operatorname{diam}(t) pprox \sqrt{8|t|\log|t|}$$
 and $H_{\max}(t) pprox \frac{\sqrt{\log|t|}}{\sqrt{2|t|}}$

• The proof involves: the analysis of the linearized operator at the cylinder, Huisken's monotonicity formula and carefully constructed barriers at the intermediate region.

Uniqueness of Ancient MCF ovals

- Work in progress: to establish such asymptotics in the non-symmetric case.
- Next Step: Establish the uniqueness of the Ancient ovals.
- Conjecture 1: The Ancient ovals with $O(I) \times O(k)$ symmetry are uniquely determined by their asymptotics at $t \to -\infty$.
- Hence: they are unique (up to dilation and translation in rescaled time).
- Conjecture 2: All Ancient ovals are $O(I) \times O(k)$ symmetric.

- Work in progress (with N. Sesum) Classify all eternal convex and complete solutions to the MCF.
- Conjecture: Eternal convex and entire graph solutions are translating solitons.
- Haslhofer: A uniformly two convex $(\lambda_1 + \lambda_2 \ge \beta H)$ and α -noncollapsed translating soliton is necessarily a bowl soliton.
- Work in progress (with Davila, delPino, Wei): We construct non-convex entire graph translating solitons in dimensions n ≥ 8.

Ancient compact solutions to the 2-dim Ricci flow

• Consider an ancient solution of the Ricci flow

(RF)
$$\frac{\partial g_{ij}}{\partial t} = -2 R_{ij}$$

on a compact manifold M^2 which exists for all time $-\infty < t < T$ and becomes singular at time T.

- In dim 2, we have $R_{ij} = \frac{1}{2}R g_{ij}$, where R is the scalar curvature.
- Hamilton (1988), Chow (1991): After re-normalization, the metric becomes spherical at t = T.
- Problem: Provide the classification of all ancient compact solutions.

Ancient compact solutions to the 2-dim Ricci flow

- Choose a parametrization $g_{_{S^2}} = d\psi^2 + \cos^2\psi \,d\theta^2$ of the limiting spherical metric.
- We parametrize our solution as $g(\cdot, t) = u(\cdot, t) g_{s^2}$.
- Then the (RF) becomes equivalent to the fast-diffusion equation:

$$u_t = \Delta_{S^2} \log u - 2$$
, on $S^2 \times (-\infty, T)$.

• Provide the classification of all ancient solutions.

Examples of compact solutions on S^2

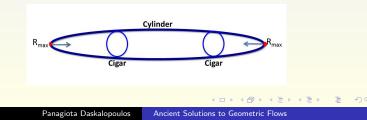

• Type I solution: the contracting spheres.

• Type II solution: the King-Rosenau solution of the form:

$$u(\psi, t) = [a(t) + b(t)\sin^2 \psi]^{-1}, t < T.$$

As $t \to -\infty$ the King-Rosenau solution looks like two cigar solitons glued together.

Theorem: (D., Hamilton, Sesum - 2012)

The only ancient solutions to the Ricci flow on S^2 are the contracting spheres and the King-Rosenau solutions.

Proof: combines geometric arguments and PDE techniques.

- i. a monotonicity formula and uniform a priori $C^{1,\alpha}$ estimates that allow us to pass to the limit as $t \to -\infty$.
- ii. geometric arguments that allow us to classify the backward limit as $t \to -\infty$.
- iii. maximum principle arguments that allow us to characterize the King-Rosenau solutions among type II solutions.
- iv. an isoperimetric inequality that allows us to characterize the contracting spheres among type I solutions.

The 3 dimensional Ricci flow - Open problems

- 3-dim Ricci flow: The analogue of the 2-dim King-Rosenau solutions have been shown to exist by G. Perelman. They are not given in closed form, they are type II and k-noncollapsed.
- Other collapsed compact solutions in closed form have been found by V.A. Fateev in a paper dated back to 1996.
- Conjecture: The only k-noncollapsed ancient and compact solutions to the 3-dim Ricci flow are the contracting spheres and the Perelman solutions.

Ancient solutions to the Yamabe flow

- We will conclude by discussing ancient solutions $g = g_{ij}$ of the Yamabe flow on S^n , $n \ge 3$.
- The Yamabe flow may be viewed as the higher dimensional analogue of the 2-dim Ricci flow.
- It is the evolution of metric $g(\cdot, t)$ conformally equivalent to the standard metric on S^n by

$$\frac{\partial g}{\partial t} = -Rg$$
 on $-\infty < t < T$

where R denotes the scalar curvature of g.

• Question: Is it possible to provide the classification of all such ancient solutions ?

The Yamabe flow - Background

• Let (M^n, g_0) , $n \ge 3$ be a compact manifold without boundary. The scalar curvature R of a metric $g = v^{\frac{4}{n-2}} g_0$ conformal to g_0 is given by

$$R = -v^{-\frac{n+2}{n-2}} \left(c_n \Delta_{g_0} v - R_0 v \right)$$

where R_0 denotes the scalar curvature of g_0 .

- R. Hamilton (1989): introduced the Yamabe flow as a parabolic approach to resolve the Yamabe problem.
- S. Brendle (2007): convergence of the normalized flow to a metric of constant scalar curvature (up to a mild technical assumption for dim n ≥ 6).
- Previous important works: Hamilton '89, Chow '92, Ye '94, Schwetlick-Struwe '2003.

Ancient solutions to the Yamabe flow on S^n

- Let $g = v^{\frac{4}{n-2}} g_{S^n}$ be an ancient solution to the Yamabe flow, which is conformal to the standard metric on S^n .
- The function v evolves by the fast diffusion equation

$$(v^{\frac{n+2}{n-2}})_t = \Delta_{S^n} v - c_n v$$
 on $S^n \times (-\infty, T)$.

• Let $g = \bar{v}^{\frac{4}{n-2}} g_{\mathbb{R}^n}$ after stereographic projection. Then,

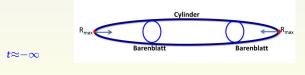

$$(\overline{v}^{\frac{n+2}{n-2}})_t = \Delta \overline{v} \quad \text{on } \mathbb{R}^n \times (-\infty, T).$$

The King Solutions

- J.King (1993): discovered non-self similar type I ancient compact solutions to the (YF) on Sⁿ in closed form.
- King solutions: $g = \hat{v}_{\kappa}(\cdot, t)^{rac{4}{n-2}} g_{\mathbb{R}^n}$, where

$$\hat{v}_{\kappa}(x,t) = \left(\mathsf{a}(t) + 2\mathsf{b}(t) \, |x|^2 + \mathsf{a}(t) |x|^4
ight)^{-rac{n-2}{4}}, \qquad x \in \mathbb{R}^n.$$

• As $t \to -\infty$ they converge (after rescaling) to two Barenblatt type self-similar solutions (shrinking solitons) joined by a long cylindrical neck.

Ancient solutions to the Yamabe flow on S^n

• Question 1:

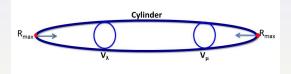

Are the contracting spheres and the King solutions the only examples of type I ancient solutions ?

• Question 2:

Are there any type II ancient solutions ?

New Type I solutions to the Yamabe flow

- Recent work: (D., del Pino, J. King and N. Sesum 2015) There exist infinite many other type I ancient solutions.
- As t → -∞ they look as two self-similar solutions v_λ, v_μ connected by a cylinder and moving with speeds λ > 0, μ > 0.

- Our solutions are not given in closed form but we show sharp asymptotics.
- In similar spirit to the work by Hamel and Nadirashvili (1999) where they construct a five parameter family of ancient solutions for the KPP equation

$$u_t = u_{xx} + f(u), \qquad x \in R.$$

Shrinking solitons with cylindrical behavior

- We look for rotationally symmetric shrinking solitons of the (YF) expressed in cylindrical coordinates $g = v^{\frac{4}{n-2}} g_{cvl}$.
- $v(x, \tau)$ satisfies (after a type I rescaling) the equation:

(*)
$$(v^{\frac{n+2}{n-2}})_{\tau} = v_{xx} - v + v^{\frac{n+2}{n-2}}.$$

Shrinking solitons (or traveling waves): ∀λ ≥ 1 there exist a solution v_λ = V_λ(x − λτ) of (*) with cylindrical behavior

$$V_{\lambda}(x) pprox 1 - C_{\lambda} e^{-\gamma_{\lambda} x}, \quad \text{ as } x o +\infty.$$

Theorem: (D., J. King and N. Sesum)
 L¹ stability of the traveling wave solutions v_λ.

Shrinking solitons with cylindrical behavior

- Consider shrinking solitons in cylindrical coordinates and after a type I scaling.
- Traveling wave to the right: $v_{\lambda,h} = V_{\lambda}(x \lambda \tau + h)$

• Traveling wave to the left: $ar{v}_{\mu,h'} = V_{\mu}(-x-\mu\, au+h')$

• Clylinder: $\xi_k(\tau) \approx 1 - k e^{\tau/2}$, as $\tau \to -\infty$.

New type I ancient solutions

• Theorem: (D., del Pino, J. King and N. Sesum - 2016) There exist a five parameter family $v_{\lambda,\mu,h,h',k}$ of type I ancient solutions of the Yamabe flow on $S^n \times (-\infty, T)$.

• In terms of the pressure function $f := v^q$, $q := -\frac{4}{n-2}$ it satisfies:

$$v^q_{\lambda,\mu,h,h',k}pprox v^q_{\lambda,h}(x, au)+\xi_k(au)^q+ar v^q_{\mu,h'}-2k$$

New type I ancient solutions - Sketch of proof

- Hamel and Nadirashvili (1999): Construct a five parameter family of ancient solutions for $u_t = u_{xx} + f(u)$ by estimating the error of approximation using heat kernel representation.
- We construct precise barriers for the pressure function $f := v^q_{\lambda,\mu,h,h',k'}, q := -\frac{4}{n-2}$:

$$w^-_{\lambda,\mu,h,h',k} := \max\left(v^q_\lambda(x-\lambda au+h),\,\xi^q_k(au),\,v^q_\mu(-x-\mu au+h')
ight)$$

$$w_{\lambda,\mu,h,h',k}^{+} := v_{\lambda}^{q} (x - \lambda \tau (1 - c e^{\frac{p-1}{p}\tau}) + h) + \xi_{k}^{q} (\tau) + v_{\mu}^{q} (-x - \mu \tau (1 - c e^{\frac{p-1}{p}\tau}) + h') - 2$$

where c = c(p). • We have

VVe have

$$w^-_{\lambda,\mu,h,h',k} \leq v^q_{\lambda,\mu,h,h',k} \leq w^+_{\lambda,\mu,h,h',k}, \quad -\infty < au < +\infty.$$

Ancient towers of moving bubbles - type II solutions

- Question: Are there any type II ancient solutions to (YF) ?
- D., del Pino and Sesum (2013): We construct a class of ancient solutions of the Yamabe flow on Sⁿ which (after re-normalization) converge as t → -∞ to a tower of n-spheres. They are rotationally symmetric.

$$t \to -\infty$$
 $t > -\infty$

- The curvature operator in these solutions changes sign and they are of type II.
- Our construction also holds for any number of bubbles.

Discussion on parabolic gluing methods

- Our construction may be viewed as a parabolic analogue of the elliptic gluing technique.
- Elliptic gluing: pioneering works by Kapouleas '90 '95 and works Mazzeo, Pacard, Pollack, Ulhenbeck.
- Brendle & Kapouleas (2014): construct new ancient compact solutions to the 4-dim Ricci flow by parabolic gluing.
- Future research direction: apply parabolic gluing on other geometric flows.

- We discussed ancient solutions to geometric parabolic PDE.
- Typical examples are either solitons or other special solutions obtained from the gluing as t → -∞ of solitons.
- The only existing classification results heavily rely on knowing the exact form of these ancient solutions.
- Future research direction: develop new techniques that allow us to characterize and construct other types of ancient or eternal solutions.
