This talk could have been titled:

Yet another Krylov method equivalent to GMRES

Many Krylov methods have been proposed over the years for solving linear systems Ax = b

Many of them can be classified as quasi-orthogonal (Q-OR) or quasi-minimum residual (Q-MR)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Q-OR: FOM, BiCG, Hessenberg, .... Q-MR: GMRES, QMR, CMRH, .... Whatever their definition, these methods share many fundamental properties

See M. Eiermann and O.G. Ernst, *Geometric aspects in the theory of Krylov subspace methods*, Acta Numerica, v 10 n 10 (2001), pp. 251–312

They differ by the basis of the Krylov space that is constructed:

- orthogonal for FOM/GMRES,
- bi-orthogonal for BiCG/QMR,
- based on an LU factorization for  $\ensuremath{\mathsf{Hessenberg}}/\ensuremath{\mathsf{CMRH}}$

#### Q-OR and Q-MR methods

We assume that we have a basis V of the Krylov space (with columns of unit norm) such that K = VU with

$$K = (b \quad Ab \quad A^2b \quad \cdots \quad A^{n-1}b)$$

*V* nonsingular with  $v_1 = b$  and *U* upper triangular We define  $H = UCU^{-1}$ , upper Hessenberg, where *C* is the companion matrix for the eigenvalues of *A*. As a consequence AV = VH. The iterates are

 $x_k = V_k y^{(k)}$ 

where  $V_k$  is the matrix of the k first columns of V. The residual  $r_k$  is

$$V_k e_1 - A V_k y^{(k)} = V_k (e_1 - H_k y^{(k)}) - h_{k+1,k} y^{(k)}_k v_{k+1} = V_{k+1} (e_1 - \underline{H}_k y^{(k)})$$

The Q-OR method is defined (provided that  $H_k$  is nonsingular) by

 $H_k y^{(k)} = e_1$ 

This annihilates the first term in the residual

In the Q-MR method  $y^{(k)}$  is computed as the solution of the least squares problem

 $\min_{y} \|e_1 - \underline{H}_k y\|$ 

where  $\underline{H}_k$  is  $(k+1) \times k$ . The vector  $z_k^M = e_1 - \underline{H}_k y^{(k)}$  is referred as the quasi-residual. The residual vector is  $r_k^M = V_{k+1} z_k^M$ 

#### Properties of Q-OR methods

We can show by induction that

$$|(U^{-1})_{1,k}| = \frac{1}{\|r_{k-1}^{O}\|}$$

The inverses of the Q-OR residual norms can be read from the first row of the inverse of U

For any Q-OR method we have the same property as for FOM

For these properties and more see:

G. Meurant and J. Duintjer Tebbens, On the convergence of Q-OR and Q-MR Krylov methods for solving nonsymmetric linear systems, BIT Numerical Mathematics, v 56 n 1 (2016), pp. 77-97

### Construction of "good" bases

We would like to find bases which lead to a "good" convergence of the  $\ensuremath{\mathsf{Q}}\xspace-\ensuremath{\mathsf{OR}}\xspace$  method

- The matrix V of the basis is related to the Krylov matrix K by K = VU with U upper triangular

- The entries of the first row of  $U^{-1}$  are the inverses of the Q-OR residual norms (up to the sign)

Constructing a "good" basis may seem easy since one can think that we can just construct any upper triangular matrix  $U^{-1}$  with entries of large modulus on the first row

But, it is not so since the columns of V have to be of unit norm

We can try directly computing  $U^{-1}$  from  $V = KU^{-1}$ 

In this way we obtain the vectors  $v_j$  straightforwardly, but, again, the columns of V have to be of unit norm

Let  $\nu_{i,j}$  be the entries of  $U^{-1}$  and

$$\mathbf{v}_k = \nu_{1,k}\mathbf{v} + \nu_{2,k}\mathbf{A}^2\mathbf{v} + \dots + \nu_{k,k}\mathbf{A}^{k-1}\mathbf{v}$$

We would like to have  $||v_k|| = 1$  and  $|v_{1,k}|$  as large as possible Can we solve this problem? Let  $\tilde{\nu}$  be the vector of the components  $\nu_{i,k}, i = 1, \dots, k$ . Then  $v_k = K \tilde{\nu}$ 

We want  $||K_k \tilde{\nu}|| = 1$ . This corresponds to

$$\tilde{\nu}^{\mathsf{T}} \mathsf{K}_k^{\mathsf{T}} \mathsf{K}_k \tilde{\nu} = \tilde{\nu}^{\mathsf{T}} \mathcal{M}_k \tilde{\nu} = 1$$

This is the equation of an (hyper) ellipsoid in  $\mathbb{R}^k$  centered at the origin

(日) (日) (日) (日) (日) (日) (日) (日)

We have to find a point on the surface of this ellipsoid with a maximum of the absolute value of the first coordinate

The solution is obtained by writing the equation of a tangent hyperplane and asking that it is orthogonal to the first axis

One can show that a solution is  $\nu_{1,k} = \sqrt{(\mathcal{M}_k^{-1})_{1,1}}$  and the other components are obtained by solving a linear system of order k-1 whose matrix and right-hand side are  $\mathcal{M}_{2:k,2:k}$  and  $-x\mathcal{M}_{2:k,1}$ 

This yields  $U^{-1}$ . If we apply Q-OR with the basis  $V = KU^{-1}$  we obtain residual vectors whose norms are

$$\|r_k^O\|^2 = rac{1}{(\mathcal{M}_{k+1}^{-1})_{1,1}}$$

These values are those that are obtained from GMRES Therefore, they are the best ones that we can get with the given Krylov subspace. In a sense we have an optimal Q-OR method

## Avoiding the use of U

The previous construction is not practical because

1) we do not want to compute  $\mathcal{M}_k$  and  $\mathcal{M}_k^{-1}$ 

2) in many cases the matrix U is almost singular and must be (numerically) avoided

Instead we would like to directly construct  $\ensuremath{\textit{H}}$  column by column. We have

$$H_j = U_j E_j U_j^{-1} + \begin{pmatrix} 0 & \cdots & 0 & \frac{1}{u_{j,j}} U_{1:j,j+1} \end{pmatrix}$$

*E<sub>j</sub>* down-shift matrix It yields

$$\sum_{j=1}^{k+1} \nu_{1,j} h_{j,k} = 0 \; \Rightarrow \; \nu_{1,k+1} = -\frac{1}{h_{k+1,k}} \sum_{j=1}^{k} \nu_{1,j} h_{j,k}$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

At step k we have already computed  $\nu_{1,j}$ , j = 1, ..., k and we would like to choose  $h_{j,k}$ , j = 1, ..., k + 1 to maximize the absolute value of  $\nu_{1,k+1}$ . But here the chosen to obtain a vector k is of unit not

But  $h_{k+1,k}$  has to be chosen to obtain a vector  $v_{k+1}$  of unit norm Let

$$\tilde{v} = Av_k - \sum_{j=1}^{\kappa} h_{j,k} v_j$$

the next basis vector is  $v_{k+1} = \tilde{v}/h_{k+1,k}$  with  $h_{k+1,k} = \|\tilde{v}\|$ 

$$|\nu_{1,k+1}| = \frac{|
u^T y|}{\|d - By\|}$$

with

$$d = Av_k, \quad B = V_k = \begin{pmatrix} v_1 & \cdots & v_k \end{pmatrix}, \quad y = \begin{pmatrix} h_{1,k} & \cdots & h_{k,k} \end{pmatrix}^T$$
$$\nu = \begin{pmatrix} \nu_{1,1} & \cdots & \nu_{1,k} \end{pmatrix}$$
We need to minimize  $1/|\nu_{1,k+1}|^2$ 

・ロト・西ト・ヨト・ヨー シック

We would like to solve

$$\gamma_{opt} = \min_{y \in \mathbb{R}^k, \nu^T y \neq 0} \frac{\|d - By\|^2}{(\nu^T y)^2}$$

The minimum is given by

$$\gamma_{opt} = \frac{\alpha}{\alpha \nu^T (B^T B)^{-1} \nu + \omega^2}$$

with  $\alpha = d^T d - d^T B(B^T B)^{-1} B^T d$  and  $\omega = d^T B(B^T B)^{-1} \nu$ Moreover, if  $\omega \neq 0$ , a solution  $y_{opt}$  of the minimization problem is given by

$$y_{opt} = (B^T B)^{-1} B^T d + \frac{\alpha}{\omega} (B^T B)^{-1} \nu$$
$$= s + \frac{\alpha}{\omega} p$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへで

This is obtained by finding the largest possible value of  $\gamma$  such that

$$\frac{1}{|\nu_{1,k+1}|^2} = \frac{\|b - By\|^2}{(\nu^T y)^2} \ge \gamma$$

which can be written in matrix form as

$$\begin{pmatrix} y^{\mathsf{T}} & 1 \end{pmatrix} \begin{pmatrix} B^{\mathsf{T}}B - \gamma\nu\nu^{\mathsf{T}} & -B^{\mathsf{T}}b \\ -b^{\mathsf{T}}B & b^{\mathsf{T}}b \end{pmatrix} \begin{pmatrix} y \\ 1 \end{pmatrix} \ge 0$$

In our case we have to solve

$$(V_k^T V_k)s = V_k^T A v_k, \quad (V_k^T V_k)p = \nu$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Properties of the optimal basis

$$\tilde{\mathbf{v}} = (I - V_k (V_k^T V_k)^{-1} V_k^T) A \mathbf{v}_k - \frac{\alpha}{\omega} V_k (V_k^T V_k)^{-1} \nu$$

$$V_{k+1}^{T} v_{k+1} = \frac{1}{\nu_{1,k+1}} \begin{pmatrix} \nu_{1,1} \\ \vdots \\ \nu_{1,k} \\ \nu_{1,k+1} \end{pmatrix}$$
$$V_{k}^{T} V_{k} = \begin{pmatrix} 1 & \frac{1}{\nu_{1,2}} & \frac{1}{\nu_{1,3}} & \cdots & \frac{1}{\nu_{1,k}} \\ \frac{1}{\nu_{1,2}} & 1 & \frac{\nu_{1,2}}{\nu_{1,3}} & \cdots & \frac{\nu_{1,2}}{\nu_{1,k}} \\ \frac{1}{\nu_{1,3}} & \frac{\nu_{1,2}}{\nu_{1,3}} & 1 & \cdots & \frac{\nu_{1,3}}{\nu_{1,k}} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{1}{\nu_{1,k}} & \frac{\nu_{1,2}}{\nu_{1,k}} & \cdots & 1 \end{pmatrix}$$

When the method converges, the basis is more and more orthogonal ・ロト・日本・モート モー うへで The inverse of  $V_k^T V_k$  is tridiagonal and the matrix  $V_k^T A V_k$  is upper triangular

$$p = (V_k^{\mathsf{T}} V_k)^{-1} \nu = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ \nu_{1,k} \end{pmatrix}$$

We will use this relation to simplify the construction of the basis vectors

The relation giving  $V_k^T V_k$  cannot be used numerically because it will lead to a discrepancy between the computed vectors  $v_j$  and the computed  $V_k^T V_k$ 

We can simplify the formulas for the new vector

$$\omega = \boldsymbol{p}^T \boldsymbol{V}_k^T \boldsymbol{A} \boldsymbol{v}_k = \nu_{1,k} \boldsymbol{v}_k^T \boldsymbol{A} \boldsymbol{v}_k$$

Let  $y_{opt} = s + \frac{\alpha}{\omega}p$ 

$$\tilde{v} = Av_k - V_k y_{opt}$$

$$= Av_k - V_k s - \frac{\alpha}{\omega} V_k p$$

$$= Av_k - V_k s - \frac{\alpha}{\omega} \nu_{1,k} v_k$$

$$= Av_k - V_k s - \frac{\alpha}{v_k^T A v_k} v_k$$

 $\mathsf{and}$ 

$$h_{1:k,k} = s + \beta e_k, \quad \beta = \frac{\alpha}{v_k^T A v_k}$$

### The Q-OR optimal algorithm

We compute incrementally the inverses of the Cholesky factors of  $V_k^T V_k$ 

Let  $v_k^A = Av_k$ 1-  $v_k^V = V_{k-1}^T v_k$ ,  $v_k^{tA} = V_k^T v_k^A$ 2-  $\ell_k = \tilde{L}_{k-1} v_k^V$ ,  $y_k^T = \ell_k^T \tilde{L}_{k-1}$ 3- if  $\ell_k^T \ell_k < 1$ ,  $\ell_{k,k} = \sqrt{1 - \ell_k^T \ell_k}$ , else  $(p_k^v)^T = y_k^T V_{k-1}^T$ ,  $\ell_{k,k} = ||v_k - p_k^v||$  end

$$ilde{L}_k = egin{pmatrix} ilde{L}_{k-1} & 0 \ -rac{1}{\ell_{k,k}}y_k^{\mathcal{T}} & rac{1}{\ell_{k,k}} \end{pmatrix}$$

5- 
$$\ell_A = \tilde{L}_k v_k^{tA}$$
,  $s = \tilde{L}_k^T \ell_A$   
6-  $\alpha = (v_k^A)^T v_k^A - \ell_A^T \ell_A$ ,  $\beta = \frac{\alpha}{(v_k^{tA})_k}$   
7-  $(h_{1,k})$ 

4-

$$h_{1:k,k} = \begin{pmatrix} h_{1,k} \\ \vdots \\ h_{k,k} \end{pmatrix} = s + \beta e_k$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ ▲□ ● ● ●

8-

$$\tilde{v} = v_k^A - V_k h_{1:k,k}, \ h_{k+1,k} = \|\tilde{v}\|, \ \nu_{1,k+1} = -\frac{1}{h_{k+1,k}} \nu^T h_{1:k,k}$$
$$\nu = (\nu_{1,1} \quad \cdots \quad \nu_{1,k+1})^T$$

9-  $v_{k+1} = \frac{1}{h_{k+1,k}}\tilde{v}$  and  $v_{k+1}^A = Av_{k+1}$ 10- if needed, solve  $H_k y^{(k)} = \|b\|e_1$  using Givens rotations,  $x_k = V_k y^{(k)}$ 

In this algorithm almost everything is expressed in terms of matrix-vector products

#### Numerical experiments

*fs* 680 1 of order 680 scaled by the inverse of its diagonal It has 2184 non zero entries. The norm of A is 3.8168 and its condition number is  $8.6944 \ 10^3$

- QOR opt 5.50626 10<sup>-15</sup>

#### A smaller matrix for the same problem, n = 100

Supg 100,  $\log_{10}$  of  $|V^T V|$ , GMRES-MGS

#### Supg 100, $\log_{10}$ of $|V^T V|$ , QOR opt

Supg 100,  $\log_{10}$  of  $|(V^T V)^{-1}|$ , QOR opt

Supg 100,  $\log_{10}$  of  $|V^T V|$ , GMRES-CGS

э

#### Conclusion

Using the properties of the Q-OR methods we were able to construct a non-orthogonal basis for which Q-OR gives the same residual norms as  $\mathsf{GMRES}$ 

The algorithm is slightly more expensive than GMRES

But, it is more parallel than GMRES-MGS and most of the operations are matrix-vector products

In many cases the maximum attainable accuracy is better than with GMRES-MGS

However, (at least theoretically), the algorithm is not breakdown-free

It remains to study its stability in finite precision arithmetic and to see how to use it on parallel computers

#### Homework

Find a good name for this method

Why not **QuORUM**?
