p-Hub Median Problem (pHM)

• Metric pHM

Instance

- a set of clients $V = \{v_1, v_2, \ldots, v_n\}$
- a set os demands $D \subseteq V \times V$
- a cost function ρ : $V \times V \to \mathbb{R}^+$
- an integer p > 0

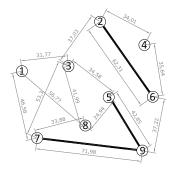

▲□▶▲□▶▲□▶▲□▶ ▲□ ● のへで

• Metric pHM

Instance

- a set of clients $V = \{v_1, v_2, \ldots, v_n\}$
- a set os demands $D \subseteq V \times V$
- a cost function $\rho: V \times V \to \mathbb{R}^+$
- an integer p > 0

• Metric pHM

Instance

- a set of clients $V = \{v_1, v_2, \ldots, v_n\}$
- a set os demands $D \subseteq V \times V$
- a cost function $\rho: V \times V \to \mathbb{R}^+$
- an integer p > 0

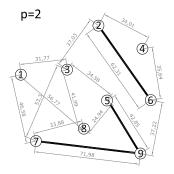

• Metric pHM

Instance

- a set of clients $V = \{v_1, v_2, \ldots, v_n\}$
- a set os demands $D \subseteq V \times V$
- a cost function $\rho: V \times V \to \mathbb{R}^+$
- an integer p > 0

Objective

Select $T \subseteq V$ of terminals, where $|T| \leq p$, and assign each demand to a terminal, in order to minimize the total cost between demands and terminals.

p-Hub Median Problem (pHM)

Theorem

K-Median is a particular case of pHM.

Theorem [Jain et. al., 2002]

K-Median has a approximation factor $\ge 1 + \frac{2}{e}$ if NP $\not\subset$ DTIME($n^{O(\log \log n)}$).

Corollary

pHM has a approximation factor $\geq 1 + \frac{2}{\rho}$ if NP $\not\subset$ DTIME($n^{O(\log \log n)}$).

p-Hub Median Problem (pHM)

Theorem

A (4 α)-approximation algorithm that opens at most $\left(\frac{2\alpha}{2\alpha-1}\right) p$ terminals, where $\alpha > 1$ is a trade off parameter.

Linear Program

- First, we preprocess the input, defining a new cost function ρ̂ such that ρ̂(d, i) = ρ(u, i) + ρ(i, v), ∀d = (u, v) ∈ D, i ∈ V.
- The integer program (IP) formulation for pHM:

	minimize	$\sum_{d \in D} \sum_{i \in V} x_{di} \hat{\rho}(d, i)$	
	subject to	$\sum_{i \in V} y_i \le p$	
(IP)		$\sum_{i\in V}^{N} x_{di} = 1,$	$\forall d \in D$
		$x_{di} \leq y_i,$	$\forall d \in D, i \in V$
		$x_{di} \in \{0, 1\},\$	$\forall d \in D, i \in V$
		$y_i \in \{0,1\},$	$\forall i \in V$

• Our algorithm uses the LP relaxation of IP 1, where $x_{di} \ge 0$ and $y_i \ge 0, \forall d \in D, i \in V$.

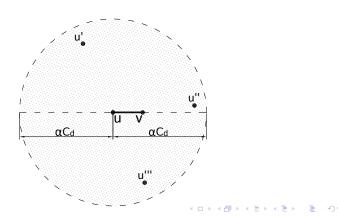

Rounding Algorithm

To each demand $d=(u, v) \in D$:

• "Mean Distance": $C_d = \sum_{i \in V} x_{di} \hat{\rho}(d, i)$

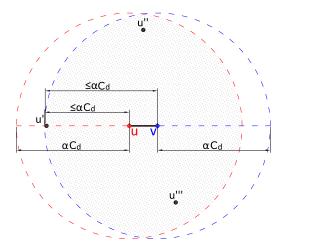

For each $u \in V$, let:

• $B(u, \alpha C_d)$

For each $d = (u, v) \in D$, let:

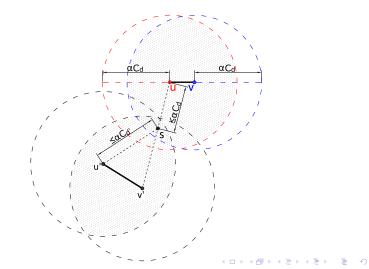

• Neighborhood: $I_d = \{u' \in B(u, \alpha C_d) \cap B(v, \alpha C_d)\}$

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ = 臣 = のへで

For each $d \in D$, let:

• *Extended neighborhood*: $\overline{V_d} = \{(u', v') \in V^2 : (u', v') \in D \text{ and } I_d \cap I_{(u', v')} \neq \emptyset\}$

▲□▶▲□▶▲□▶▲□▶ □ のQで

Rounding Algorithm

Algorithm 1: Rounding Algorithm.

- 1 Solve the LP and use it to compute the C_d values
- 2 $T := \{\}$
- $3 \overline{D} := D$
- 4 while $\overline{D} \neq \emptyset$ do
- Choose $d = (u, v) \in \overline{D}$ with the lowest value of C_d 5
- $T := T \cup \{u\}$ 6
- for $(u', v') \in \overline{D}$ do 7
- if $(u' \in \overline{V_d})$ and $(v' \in \overline{V_d})$ then 8 $\overline{D} := \overline{D} \setminus (u', v')$
- 9
- $\overline{D} := \overline{D} \setminus (u, v)$ 10

return T 11

Conclusions and Future Works

- We got a (4 α)-approximation algorithm, with $\alpha > 1$, that opens at most $\left(\frac{2\alpha}{2\alpha-1}\right) p$ terminals.
- We used the rounding technique of linear programs.
- As future works: opening the right number of terminals and improve the approximation factor.
