Discrete model: $\underline{X} = (X_v, v \in V) \in \mathcal{I} = \times_{v \in V} \mathcal{I}_v$

$p_{\underline{i}} := \mathbb{P}(\underline{X} = \underline{i}) > 0, \underline{i} \in \mathcal{I}$ and $\#\mathcal{I} < \infty$

- *marginal probability*: for $A \subset V$ denote $\underline{X}_A = (X_v, v \in A)$,

$$p_{\underline{i}_A}^A := \mathbb{P}(\underline{X}_A = \underline{i}_A) = \sum_{\underline{i}_{A^c} \in \mathcal{I}_{A^c}} p(\underline{i}), \quad \underline{i}_A \in \mathcal{I}_A := \times_{v \in A} \mathcal{I}_v,$$

- *conditional probability*: for $A, B \subset V$ disjoint

$$p_{\underline{k}|\underline{m}}^{A|B} := \frac{p_{(\underline{k}, \underline{m})}^{A \cup B}}{p_{\underline{m}}^B}, \quad (\underline{k}, \underline{m}) \in \mathcal{I}_{A \cup B}.$$

- for $A, B, S \subset V$ disjoint $\underline{X}_A \perp\!\!\!\perp \underline{X}_B \mid \underline{X}_S$ if

$$p_{(\underline{k}, \underline{m})|\underline{n}}^{A \cup B|S} = p_{\underline{k}|\underline{n}}^{A|S} p_{\underline{m}|\underline{n}}^{B|S}, \quad (\underline{k}, \underline{m}, \underline{n}) \in \mathcal{I}_{A \cup B \cup S}.$$

Notation: $\mathbf{A} \perp\!\!\!\perp \mathbf{B} \mid \mathbf{S}$

Markov property wrt an undirected graph $G = (V, E)$

Distribution $p = (p_i)_{i \in \mathcal{I}}$, is Markov wrt G if anyone of 2 conditions holds (**equivalent** since $p_i > 0 \forall i \in \mathcal{I}$)

- $v \perp\!\!\!\perp w \mid V \setminus \{v, w\}$ if only $v \sim w \notin E$,
- **Hammersley-Clifford factorization**

$$p_i = \prod_{A \subset V: G_A \text{ is complete}} \psi_A(i_A) \quad \forall i \in \mathcal{I}$$

for some functions ψ_A .

G_A denotes the subgraph induced in G by $A \subset V$.

Markov property wrt a DAG

A DAG $\mathcal{G} = \mathcal{G}(G, \text{pa})$ with skeleton $G = (V, E)$ is defined by parent function $\text{pa} : V \rightarrow 2^V$

$$\text{pa}(v) = \{w \in V : w \rightarrow v\}, \quad v \in V.$$

A distribution $p = (p_{\underline{i}})_{\underline{i} \in \mathcal{I}}$ is Markov wrt \mathcal{G} if any of 2 **equivalent** conditions holds:

- $\forall v \in V$

$$v \perp\!\!\!\perp n\partial(v) \setminus \text{pa}(v) \mid \text{pa}(v),$$

where $n\partial(v) = \{w \in V : \neg(v \rightarrow u_1 \rightarrow \dots \rightarrow u_k \rightarrow w)\}$;

- recursive factorization:

$$p_{\underline{i}} = \prod_{v \in V} p_{i_v}^{v \mid \text{pa}(v)}, \quad \underline{i} \in \mathcal{I}.$$

- 1 Markov properties in graphical language
- 2 Morality: decomposable models**
- 3 Bayesian perspective: hyper-Dirichlet and beyond
- 4 Global and local parameter independence: characterizations
- 5 Immoralities: from DAGs to essential graphs through CCC
- 6 Literature

Who is moral?

Let $G = (V, E)$ be a decomposable (**chordal**) undirected graph, i.e. any loop of size ≥ 4 has a chord.

A DAG $\mathcal{G} = \mathcal{G}(G, \text{pa})$ is **moral** if

$$\forall v \in V \quad G_{\text{pa}(v)} \text{ is complete.}$$

Example:

$$a \rightarrow b \rightarrow c, \quad a \leftarrow b \leftarrow c, \quad a \leftarrow b \rightarrow c$$

are moral DAGs.

$$a \rightarrow b \leftarrow c$$

is not.

Markov factorizations for chordal $G = (V, E)$

\mathcal{C} - set of cliques (maximal complete subgraphs);

\mathcal{S} - set of separators (minimal complete subgraphs removal of which makes the rest of G disconnected).

A distribution $p = (p_{\underline{i}}, \underline{i} \in \mathcal{I})$

- is Markov wrt undirected chordal graph $G = (V, E)$, i.e.

$$p_{\underline{i}} = \frac{\prod_{C \in \mathcal{C}} p_{i_C}^C}{\prod_{S \in \mathcal{S}} p_{i_S}^S}, \quad \underline{i} \in \mathcal{I}.$$

iff

- it is Markov wrt a moral DAG $\mathcal{G} = \mathcal{G}(G, \text{pa})$, i.e.

$$p_{\underline{i}} = \prod_{v \in V} p_{i_v | i_{\text{pa}(v)}}^{v | \text{pa}(v)}, \quad \underline{i} \in \mathcal{I};$$

iff

- it is Markov wrt any moral DAG $\mathcal{G} = \mathcal{G}(G, \text{pa})$.

- 1 Markov properties in graphical language
- 2 Morality: decomposable models
- 3 Bayesian perspective: hyper-Dirichlet and beyond**
- 4 Global and local parameter independence: characterizations
- 5 Immoralities: from DAGs to essential graphs through CCC
- 6 Literature

Multinomial law for cell counts

Let $\underline{X}_1, \dots, \underline{X}_n$ be iid with distribution $\rho = (\rho_{\underline{i}})_{\underline{i} \in \mathcal{I}}$. Let

$$M_{\underline{i}} = \sum_{j=1}^n \mathbb{I}(\underline{X}_j = \underline{i}), \quad \underline{i} \in \mathcal{I}.$$

Then $M = (M_{\underline{i}}, \underline{i} \in \mathcal{I})$ has a multinomial distribution, $\text{mn}_{\mathcal{I}}(n, \rho)$, i.e.

$$\mathbb{P}(M = m) = \binom{n}{m} \prod_{\underline{i} \in \mathcal{I}} \rho_{\underline{i}}^{m_{\underline{i}}},$$

$$m = (m_{\underline{i}}, \underline{i} \in \mathcal{I}) \in \mathbb{N}^{\#\mathcal{I}}, \quad \sum_{\underline{i} \in \mathcal{I}} m_{\underline{i}} = n.$$

In the Bayesian approach the parameter, $\rho = (\rho_{\underline{i}}, \underline{i} \in \mathcal{I})$, becomes a random vector, $\mathbf{p} = (\mathbf{p}_{\underline{i}}, \underline{i} \in \mathcal{I})$.

Markov property wrt complete G means nothing!

The only restrictions on \mathbf{p} are:

$$\mathbf{p}_{\underline{i}} > 0, \quad \underline{i} \in \mathcal{I}, \quad \text{and} \quad \sum_{\underline{i} \in \mathcal{I}} \mathbf{p}_{\underline{i}} = 1.$$

A standard prior law is **Dirichlet** $D_{\mathcal{I}}(\alpha_{\underline{i}}, \underline{i} \in \mathcal{I})$ defined e.g. by its moments

$$\mathbb{E} \prod_{\underline{i} \in \mathcal{I}} \mathbf{p}_{\underline{i}}^{r_{\underline{i}}} = \frac{\prod_{\underline{i} \in \mathcal{I}} (\alpha_{\underline{i}})^{r_{\underline{i}}}}{(|\alpha|)^{|\mathbf{r}|}},$$

where $(r_{\underline{i}})_{\underline{i} \in \mathcal{I}} \in \mathbb{N}^{\#\mathcal{I}}$, $|\mathbf{c}| = \sum_{\underline{i} \in \mathcal{I}} \mathbf{c}_{\underline{i}}$ and $(\mathbf{c})^{\mathbf{k}} = \frac{\Gamma(\mathbf{c} + \mathbf{k})}{\Gamma(\mathbf{c})}$.

Conjugacy: If $M|\mathbf{p}$ is multinomial $\text{mn}_{\mathcal{I}}(n, \mathbf{p})$ and $\mathbf{p} \sim D_{\mathcal{I}}(\alpha_{\underline{i}}, \underline{i} \in \mathcal{I})$, then

$$\mathbf{p}|M \sim D_{\mathcal{I}}(\alpha_{\underline{i}} + M_{\underline{i}}, \underline{i} \in \mathcal{I}).$$

The easiest non-trivial case

Let $G = \mathbf{1} \sim \mathbf{2} \sim \mathbf{3}$, $\mathcal{I} = \{0, 1\}^3$ and let

$$p = (p_{ijk} = \mathbb{P}(X_1 = i, X_2 = j, X_3 = k), \quad i, j, k \in \{0, 1\}).$$

p is Markov wrt $\mathbf{1} \sim \mathbf{2} \sim \mathbf{3}$:

$$p_{ijk} = \frac{\mathbb{P}(X_1=i, X_2=j) \mathbb{P}(X_2=j, X_3=k)}{\mathbb{P}(X_2=j)}$$

iff it is Markov wrt $\mathbf{1} \rightarrow \mathbf{2} \rightarrow \mathbf{3}$:

$$p_{ijk} = \mathbb{P}(X_1 = i) \mathbb{P}(X_2 = j | X_1 = i) \mathbb{P}(X_3 = k | X_2 = j)$$

iff it is Markov wrt $\mathbf{1} \leftarrow \mathbf{2} \rightarrow \mathbf{3}$:

$$p_{ijk} = \mathbb{P}(X_1 = i | X_2 = j) \mathbb{P}(X_2 = j) \mathbb{P}(X_3 = k | X_2 = j).$$

5-dimensional manifold in 8-dimensional space

By calculation it follows that $p = (p_{ijk})$ is Markov iff

$$p_{101} = \frac{p_{100}p_{001}}{p_{000}} \quad \text{and} \quad p_{111} = \frac{p_{110}p_{011}}{p_{010}}.$$

One needs a probability measure on 5-dimensional manifold in 8-dimensional space defined by the conditions:

$$x_i > 0, \quad i = 0, \dots, 7,$$

$$\sum_{i=0}^7 x_i = 1,$$

$$x_5 = \frac{x_4 x_1}{x_0}, \quad x_7 = \frac{x_6 x_3}{x_2}.$$

Dawid & Lauritzen (AS'93) to the rescue!

Let $G = (V, E)$ be a chordal graph with cliques \mathcal{C} and separators \mathcal{S} . Then \mathbf{p} has a hyper-Dirichlet distribution $\text{HD}_G(\nu_{\underline{i}_C}^{\mathcal{C}}, \underline{i}_C \in \mathcal{I}_C, \mathcal{C} \in \mathcal{C})$ if for any $r = (r_{\underline{i}}, \underline{i} \in \mathcal{I}) \in \mathbb{N}^{\#\mathcal{I}}$,

$$\mathbb{E} \prod_{\underline{i} \in \mathcal{I}} \mathbf{p}_{\underline{i}}^{r_{\underline{i}}} = \frac{\prod_{\mathcal{C} \in \mathcal{C}} \prod_{\underline{i}_C \in \mathcal{I}_C} (\nu_{\underline{i}_C}^{\mathcal{C}})^{r_{\underline{i}_C}^{\mathcal{C}}}}{\prod_{\mathcal{S} \in \mathcal{S}} (\mu_{\underline{i}_S}^{\mathcal{S}})^{r_{\underline{i}_S}^{\mathcal{S}}}},$$

where for any $\mathcal{S} \in \mathcal{S}$ and $\underline{m} \in \mathcal{I}_S$

$$\mu_{\underline{m}}^{\mathcal{S}} = \sum_{\underline{n} \in \mathcal{I}_{C \setminus S}} \nu_{(\underline{m}, \underline{n})}^{\mathcal{C}} \quad \text{if only } \mathcal{S} \subset \mathcal{C} \in \mathcal{C}.$$

Here we assume that $\emptyset \in \mathcal{S}$, $\mathcal{I}_{\emptyset} = \{0\}$ and thus

$$\mu_0^{\emptyset} = \sum_{\underline{m} \in \mathcal{I}_C} \nu_{\underline{m}}^{\mathcal{C}} \quad \forall \mathcal{C} \in \mathcal{C} \quad \text{and} \quad r_0^{\emptyset} = \sum_{\underline{i} \in \mathcal{I}} r_{\underline{i}} =: |r|.$$

HD_G is conjugate in multinomial model

- If $\mathbb{P}(\underline{X} = \underline{i} | \mathbf{p}) = \mathbf{p}_{\underline{i}}$, $\underline{i} \in \mathcal{I}$, and $\mathbf{p} \sim \text{HD}_G$ then \mathbf{p} , the conditional distribution $\underline{X} | \mathbf{p}$, is Markov wrt to G .
- If G is a complete then $\mathcal{C} = \{G\}$ and $\mathcal{S} = \{\emptyset\}$, Thus moments formula imply: $\text{HD}_G = D_{\mathcal{I}}$.
- Let $M | \mathbf{p} \sim \text{mn}_{\mathcal{I}}(n, \mathbf{p})$ and $\mathbf{p} \sim \text{HD}_G(\nu_{\underline{k}}^{\mathcal{C}}, \underline{k} \in \mathcal{I}_{\mathcal{C}}, \mathcal{C} \in \mathcal{C})$. By the generalized Bayes rule

$$\mathbb{E} \left(\prod_{\underline{i} \in \mathcal{I}} \mathbf{p}_{\underline{i}}^{r_{\underline{i}}} \middle| M = m \right) = \frac{\mathbb{E} \prod_{\underline{i} \in \mathcal{I}} \mathbf{p}_{\underline{i}}^{m_i + r_{\underline{i}}}}{\mathbb{E} \prod_{\underline{i} \in \mathcal{I}} \mathbf{p}_{\underline{i}}^{m_i}} = \frac{\prod_{\mathcal{C} \in \mathcal{C}} \prod_{\underline{i}_{\mathcal{C}} \in \mathcal{I}_{\mathcal{C}}} (\nu_{\underline{i}_{\mathcal{C}}}^{\mathcal{C}} + m_{\underline{i}_{\mathcal{C}}}^{\mathcal{C}})^{r_{\underline{i}_{\mathcal{C}}}^{\mathcal{C}}}}{\prod_{\mathcal{S} \in \mathcal{S}} (\mu_{\underline{i}_{\mathcal{S}}}^{\mathcal{S}} + m_{\underline{i}_{\mathcal{S}}}^{\mathcal{S}})^{r_{\underline{i}_{\mathcal{S}}}^{\mathcal{S}}}}$$

since $(\mathbf{a})^{\mathbf{i} + \mathbf{j}} = (\mathbf{a})^{\mathbf{i}} (\mathbf{a} + \mathbf{i})^{\mathbf{j}}$. Thus

$$\mathbf{p} | M \sim \text{HD}_G(\nu_{\underline{i}_{\mathcal{C}}}^{\mathcal{C}} + M_{\underline{i}_{\mathcal{C}}}^{\mathcal{C}}, \underline{i}_{\mathcal{C}} \in \mathcal{I}_{\mathcal{C}}, \mathcal{C} \in \mathcal{C}),$$

where $M_{\underline{i}_{\mathcal{C}}}^{\mathcal{C}}$ are marginal counts.

Directional properties of $\mathbf{p} \sim \text{HD}_G$ for any moral DAG

- **Parameters Independence (PI):** Random conditional probabilities

$$\mathbf{p}_{i_{\text{pa}(v)}}^{v|\text{pa}(v)} := \left(\mathbf{p}_{i_v|i_{\text{pa}(v)}}^{v|\text{pa}(v)}, i_v \in \mathcal{I}_v \right), \quad i_{\text{pa}(v)} \in \mathcal{I}_{\text{pa}(v)}, v \in V$$

are independent. (global and local independence of parameters - **two in one!**)

- **Dirichlet conditionals (DC):** All random vectors

$$\mathbf{p}_{i_{\text{pa}(v)}}^{v|\text{pa}(v)}, \quad i_{\text{pa}(v)} \in \mathcal{I}_{\text{pa}(v)}, v \in V$$

have classical Dirichlet laws.

If \mathbf{p} is Markov wrt to G and satisfies PI and DC for a given DAG $\mathcal{G} = \mathcal{G}(G, \text{pa})$ we say that its law is **\mathcal{G} -Dirichlet**.

Can one determine HD_G through PI and DC?

Let $G = (V, E)$ be chordal. Let \mathbf{p} , Markov wrt G , has a \mathcal{G} -Dirichlet law for **any** moral $\mathcal{G} = \mathcal{G}(G, \text{pa})$. Then **PI** implies

$$\mathbb{E} \prod_{i \in \mathcal{I}} \mathbf{p}_i^{r_i} = \prod_{v \in V} \prod_{\underline{k} \in \mathcal{I}_{\text{pa}(v)}} \mathbb{E} \prod_{m \in \mathcal{I}_v} \left[\mathbf{p}_{m|\underline{k}}^{v|\text{pa}(v)} \right]^{r_{(k,m)}^{q(v)}},$$

where $q(v) = \text{pa}(v) \cup \{v\}$.

Since by **DC**

$$\mathbf{p}_{\underline{k}}^{v|\text{pa}(v)} \sim D_{\mathcal{I}_v}(\alpha_{m|\underline{k}}^{v|\text{pa}(v)}), \quad m \in \mathcal{I}_v, \quad \underline{k} \in \mathcal{I}_{\text{pa}(v)}, \quad v \in V,$$

it follows that

$$\mathbb{E} \prod_{i \in \mathcal{I}} \mathbf{p}_i^{r_i} = \prod_{v \in V} \prod_{\underline{k} \in \mathcal{I}_{\text{pa}(v)}} \frac{\prod_{m \in \mathcal{I}_v} \left(\alpha_{m|\underline{k}}^{v|\text{pa}(v)} \right)^{r_{(k,m)}^{q(v)}}}{\left(\alpha_{\underline{k}}^{v|\text{pa}(v)} \right)^{r_{\underline{k}}^{\text{pa}(v)}}}. \quad (1)$$

\mathcal{P} -Dirichlet distribution

Let \mathcal{P} be a family of moral DAGs with a chordal skeleton G .

If the law of \mathbf{p} is \mathcal{G} -Dirichlet for any $\mathcal{G} \in \mathcal{P}$ we call it **\mathcal{P} -Dirichlet distribution**.

To describe its properties we need to

- define several **new objects**;
- prove several **new results**!

No time ! See H. Massam & JW, AS'16.

Here we concentrate on HD_G !

When \mathcal{P} -Dirichlet is a hyper-Dirichlet?

Proposition

Let \mathcal{P} be a family of moral DAGs, with a chordal skeleton $G = (V, E)$ with cliques \mathcal{C} and separators \mathcal{S} .

Let

$$\bigcap_{G \in \mathcal{P}} \text{pa}(V) = \mathcal{S};$$

- \mathcal{P} be a **pairing family**, i.e.

$$\forall S \in \mathcal{S}, C \in \mathcal{C} \quad \text{such that} \quad S \subset C$$

$$(\exists G \in \mathcal{P}, \exists v \in C \setminus S) : \quad S = \text{pa}(v).$$

Then any \mathcal{P} -Dirichlet distribution is a HD_G distribution.

- 6 Literature

Heckerman, Geiger, Chickering, *ML*'95, Geiger, Heckerman, *AS*'97

$G = (V, E)$ - complete graph, $V = \{1, \dots, d\}$.

$\mathcal{G} = \mathcal{G}(G, \text{pa})$ corresponds to permutation $\sigma \in \mathcal{S}_d$:

$$\text{pa}(\sigma_1) = \emptyset, \quad \text{pa}(\sigma_k) = \{\sigma_1, \dots, \sigma_{k-1}\}, \quad k = 2, \dots, d.$$

Theorem

G - complete, \mathbf{p} has

a "smooth" density, which is strictly positive on the unit simplex.

If \mathbf{p} satisfies the PI condition for 2 DAGs:

$$\mathcal{G} \equiv \sigma = (1, 2, \dots, d) \quad \text{and} \quad \mathcal{G}' \equiv \sigma' = (d, 1, 2, \dots, d-1),$$

then its distribution is a classical Dirichlet.

Why "smooth" densities? Why densities at all? Why such two DAGs \mathcal{G} and \mathcal{G}' ? Why complete G ?

When do PI conditions yield HD_G distribution?

\mathcal{P} - family of DAGs with skeleton $G = (V, E)$

Separating family if $\forall v \in V$

$$\exists \mathcal{G}, \mathcal{G}' \in \mathcal{P} : \text{pa}(v) \neq \text{pa}'(v).$$

Theorem

Let \mathcal{P} be a family of moral DAGs, with a chordal skeleton $G = (V, E)$. Assume that \mathcal{P} is **pairing**, **separating** and

$$\bigcap_{\mathcal{G} \in \mathcal{P}} \text{pa}(V) = \mathcal{S} \quad (\text{set of separators}).$$

If $\forall \mathcal{G} \in \mathcal{P}$ PI holds for \mathbf{p} then \mathbf{p} has a HD_G law.

How to extend GHC theorem for complete graphs?

Theorem

Let \mathbf{p} be a vector of random probabilities. Let G be a complete graph with vertices $\{1, \dots, d\}$. Consider 2 DAGs $\mathcal{G} \equiv \sigma \in \mathcal{S}_d$ and $\mathcal{G}' \equiv \sigma' \in \mathcal{S}_d$:

$$\sigma(\{1, \dots, j\}) \neq \sigma'(\{1, \dots, j\}), \quad j = 1, \dots, d - 1.$$

If \mathbf{p} satisfies PI conditions wrt to \mathcal{G} and \mathcal{G}' then its law is classical Dirichlet.

The case of GHC'95 and GH'97:

$$\sigma(\{1, \dots, j\}) = \{1, \dots, j\} \quad \text{and} \quad \sigma'(\{1, \dots, j\}) = \{d, 1, \dots, j-1\}.$$

Moral DAGs on T -ree and PI characterization of HD_T

$T = (V, E)$ - tree; L set of leaves of T .

A moral DAG $\mathcal{G} = \mathcal{G}(T, \mathbf{p}\alpha)$ is determined by its source vertex $v_0 \in V$ - we write $\mathcal{G} = \mathcal{G}_{v_0}$.

Theorem

Let \mathbf{p} be a vector of random probabilities, Markov wrt a tree T .

If \mathbf{p} satisfies the PI condition wrt to \mathcal{G}_{v_0} for all $v_0 \in L$, then its law is a hyper-Dirichlet HD_T -distribution.

Example: If $T: 1 \sim \dots \sim d$ is a chain, then PI wrt 2 DAGs:

$$\mathcal{G}_1 = 1 \rightarrow \dots \rightarrow d \quad \text{and} \quad \mathcal{G}_d = 1 \leftarrow \dots \leftarrow d$$

characterizes HD_T law.

Who is immoral?

$G = (V, E)$ - undirected graph

Γ - family of all DAGs with skeleton G

- Triplet of vertices $(a; b, c)$ - **immorality** in $\mathcal{G} \in \Gamma$ if

$$\text{pa}(a) \supset \{b, c\} \notin E.$$

- $\mathcal{G}, \mathcal{G}' \in \Gamma$ are **graphically (morally?)** equivalent, $\mathcal{G} \sim \mathcal{G}'$, iff they have identical sets of immoralities.

$\text{ES}(G) = \Gamma / \sim$ - equivalence classes of \sim .

Essential graph as Markov equivalence class

Any $[\mathcal{G}] \in \text{ES}$ with skeleton $G = (V, E)$ can be represented by a mixed graph \mathcal{E} with vertices V and edges:

- **directed** $\mathbf{a} \rightarrow \mathbf{b}$, if $a \rightarrow b \in E'$ for any $\mathcal{G}' = (V, E') \in [\mathcal{G}]$.
- **undirected** $\mathbf{a} \sim \mathbf{b}$, otherwise, if only $a \sim b \in E$

$\mathcal{E} \equiv [\mathcal{G}]$ is called an **essential graph**.

Proposition (Markov equivalence classes)

Let $\mathcal{E} \equiv [\mathcal{G}]$ be an essential graph.

A probability p is Markov wrt to \mathcal{G} iff it is Markov wrt to any DAG in $\mathcal{E} \equiv [\mathcal{G}]$ (i.e. to any DAG sharing immoralities with \mathcal{G}).

Essential graphs are special **chain graphs**.

Chain graph $-G = (V, E, \text{pa}, \mathcal{T}, \mathcal{D}, \text{pa}_{\mathcal{D}})$:

Chain graph is a mixed graph with no (partially) directed cycles.

- pa - parent function:

$$\text{pa}(b) = \{a \in V : a \rightarrow b \in E\}, \quad b \in V;$$

- $v \equiv w$ if there exists an undirected path in G connecting $v, w \in V$;
- $(V / \equiv) =: \mathcal{T} \ni \tau$ - **chain component** (CC);
- \mathcal{D} - **DAG of chain components** with parent function $\text{pa}_{\mathcal{D}}$:

$$\text{pa}_{\mathcal{D}}(\tau) = \{\sigma \in \mathcal{T} : \sigma \cap \text{pa}(\tau) \neq \emptyset\} \quad \left(\text{pa}(\tau) = \bigcup_{\mathbf{v} \in \tau} \text{pa}(\mathbf{v}) \right).$$

Andersson, Madigan, Perlman AS'97

G - mixed graph

- $a \rightarrow b \sim c$ - **flag** in G if $G_{abc} = a \rightarrow b \sim c$;
- $a \rightarrow b$ - **strongly protected** in G if one of
 - $a \rightarrow b \leftarrow c$, (immorality)
 - $c \rightarrow a \rightarrow b$, (compelled arrow)
 - $a \rightarrow c \rightarrow b$ and $a \rightarrow b$, (compelled arrow)
 - $a \sim c_i \rightarrow b$, $i = 1, 2$, and $a \rightarrow b$ (compelled arrow)

is an induced subgraph in G .

Theorem (AMP)

A mixed graph G is an essential graph iff G is a chain graph with chordal CCs;

- G has no flags;
- all arrows of G are strongly protected.

A new characterization of essential graphs

Theorem

A mixed graph G is an essential graph iff it is a chain graph $G = (V, E, \text{pa}, \mathcal{T}, \mathcal{D}, \text{pa}_{\mathcal{D}})$ with chordal CCs;
for any $\tau \in \mathcal{T}$

(I) $\text{pa}(v) = \text{pa}(\tau), \quad v \in \tau;$

(II) $\forall \sigma \in \text{pa}_{\mathcal{D}}(\tau)$

$$\text{pa}(\sigma) = \text{pa}(\tau) \setminus \sigma \quad \Rightarrow \quad G_{\sigma \cap \text{pa}(\tau)} \text{ is not complete.}$$

Following Frydenberg'90

\mathcal{P} - family of DAGs with skeleton $G = (V, E)$

$G^{\mathcal{P}} = (V, E_{\mathcal{P}})$ - chain graph with $E_{\mathcal{P}}$ defined in two steps:

F1 • if $a \rightarrow b$ in any $\mathcal{G} \in \mathcal{P}$ then

$$a \rightarrow b \in \tilde{E}_{\mathcal{P}};$$

• otherwise, if $a \sim b \in E$ then

$$a \sim b \in \tilde{E}_{\mathcal{P}}.$$

$(V, \tilde{E}_{\mathcal{P}})$ **may not be a chain graph**

F2 $E_{\mathcal{P}}$ inherits edges from $\tilde{E}_{\mathcal{P}}$ except:

if $a \rightarrow b \in \tilde{E}_{\mathcal{P}}$ is in a (partially) directed cycle, then

$$a \sim b \in E_{\mathcal{P}}.$$

q (uasi)-essential graphs

Proposition

Let $\mathcal{P} \subset [\mathcal{G}] \equiv \mathcal{E}$. Then for $G^{\mathcal{P}} = (V, E, \text{pa}, \mathcal{T})$

- 1 all its CCs are chordal;
- 2 $\text{pa}(v) = \text{pa}(\tau)$, $v \in \tau \in \mathcal{T}$. **i.e. (I) or "no flags"**

Definition

A chain graph G satisfying (1) and (2) is called **quasi-essential**.

Proposition

If G is a q -essential graph then there exists a family \mathcal{P} of Markov equivalent DAGs (with skeletons as G) such that

$$G = G^{\mathcal{P}}.$$

Then quasi-essential G is Markov equivalent to $\mathcal{E} \equiv [\mathcal{G}]$, $\mathcal{G} \in \mathcal{P}$.

What is condition (II) responsible for ?

$G = (V, E, \text{pa}, \mathcal{T}, \mathcal{D}, \text{pa}_{\mathcal{D}})$ - a chain graph

If (II) does not hold for $\sigma, \tau \in \mathcal{T}$:

$$\begin{cases} \sigma \in \text{pa}_{\mathcal{D}}(\tau), \\ \text{pa}(\sigma) = \text{pa}(\tau) \setminus \sigma, \\ G_{\sigma \cap \text{pa}(\tau)} \text{ is complete,} \end{cases} \quad (2)$$

then

$$\psi_{\sigma, \tau}(G) = G' = (V, E')$$

is a mixed graph with E' defined as follows:

- $\forall w \in \sigma$ and $\forall v \in \tau$

$$\psi_{\sigma, \tau}(w \rightarrow v) = w \sim v;$$

- other edges of E' are inherited from E .

$\psi_{\sigma,\tau}(G)$ for q -essential G

Proposition

Let G as above be a q -essential graph and $G' = \psi_{\sigma,\tau}(G)$ for $\sigma, \tau \in \mathcal{T}$ satisfying (2).

Then $G' = (V, E, \text{pa}', \mathcal{T}', \mathcal{D}', \text{pa}_{\mathcal{D}'})$ is a q -essential graph with

$$\text{pa}'(v) = \text{pa}'(\rho) = \begin{cases} \text{pa}(\rho), & v \in \rho \neq \tau, \\ \text{pa}(\tau) \setminus \sigma, & v \in \rho = \tau, \end{cases}$$

$\mathcal{T}' = (\mathcal{T} \setminus \{\sigma, \tau\}) \cup \{\sigma \cup \tau\}$ and

$$\text{pa}_{\mathcal{D}'}(\rho) = \begin{cases} \text{pa}_{\mathcal{D}}(\sigma), & \text{if } \rho = \sigma \cup \tau, \\ (\text{pa}_{\mathcal{D}}(\rho) \setminus \{\tau\}) \cup \{\sigma \cup \tau\}, & \text{if } \rho \in \mathcal{T} \text{ and } \tau \in \text{pa}_{\mathcal{D}}(\rho), \\ \text{pa}_{\mathcal{D}}(\rho), & \text{otherwise.} \end{cases}$$

Moreover, G' and G are in the same Markov equivalence class.

CCC algorithm $\sim O(n^3)$

- alternative to AMP'97 $\sim O(n^6)$

CCC algorithm: from DAG \mathcal{G} to $\mathcal{E} \equiv [\mathcal{G}]$.

1 $G_0 = \mathcal{G} = \mathcal{G}(G, \text{pa})$;

for $k = 0, 1, \dots$

2 G_k - q -essential graph with CCs set \mathcal{T}_k ;

choose $\sigma, \tau \in \mathcal{T}_k$ satisfying (2) and set

$$G_{k+1} = \psi_{\sigma, \tau}(G_k);$$

3 if

$k^* = \min\{k : \text{no chain components } \sigma, \tau \in \mathcal{T}_k \text{ satisfy (2)}\}$.

then $G_{k^*} = \mathcal{E} \equiv [\mathcal{G}]$ and the algorithm stops.
