Gibbs Sampling

Hamiltonian Monte Carlo

Markov Chain Monte Carlo Methods The Metropolis-Hastings Algorithm Monte Carlo by Markov Chains

Running Monte Carlo via Markov Chains

Far from necessary to use a sample from the distribution f to approximate the integral

$$\Im = \int h(x) f(x) dx \; ,$$

as sample from different target(s) g can be exploited in importance sampling version:

$$\hat{\mathfrak{I}} = 1/n \sum_{i=1}^{n} h(x_i) \underbrace{f(x_i)/g(x_i)}_{\text{importance weight}}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

- The Metropolis-Hastings Algorithm

Monte Carlo by Markov Chains

Running Monte Carlo via Markov Chains

Far from necessary to use a sample from the distribution f to approximate the integral

$$\Im = \int h(x) f(x) dx \; ,$$

as non-i.i.d. sample $X_1, \ldots, X_n \sim f$ produced by using an ergodic Markov chain with stationary distribution f

Monte Carlo by Markov Chains

Running Monte Carlo via Markov Chains (2)

Idea

For an arbitrary starting value $x^{(0)}$, an ergodic chain $(X^{(t)})$ is generated using a transition kernel with stationary distribution f

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

Monte Carlo by Markov Chains

Running Monte Carlo via Markov Chains (2)

Idea

For an arbitrary starting value $x^{(0)},$ an ergodic chain $(X^{(t)})$ is generated using a transition kernel with stationary distribution f

- Insures the convergence in distribution of $(X^{(t)})$ to a random variable from f.
- ► For a "large enough" T₀, X^(T₀) can be considered as distributed from limiting distribution f
- Produce a *dependent* sample X^(T₀), X^(T₀+1), ..., which is generated from f, sufficient for most approximation purposes

— The Metropolis-Hastings Algorithm

Monte Carlo by Markov Chains

Running Monte Carlo via Markov Chains (2)

- Insures the convergence in distribution of $(X^{(t)})$ to a random variable from f.
- ► For a "large enough" T₀, X^(T₀) can be considered as distributed from limiting distribution f
- Produce a *dependent* sample X^(T₀), X^(T₀+1), ..., which is generated from f, sufficient for most approximation purposes

Problem:

How can one build a Markov chain with a given stationary distribution?

- The Metropolis-Hastings Algorithm

└─ Metropolis–Hastings

The Metropolis–Hastings algorithm

Basics The algorithm uses the **objective** (target) density

and a conditional density

q(y|x)

called the instrumental (or proposal) distribution

[Metropolis & al., 1953]

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

-

- The Metropolis-Hastings Algorithm

-Metropolis-Hastings

The MH algorithm

Algorithm (Metropolis–Hastings) Given $x^{(t)}$. 1. Generate $Y_t \sim q(y|x^{(t)})$. 2. Take $X^{(t+1)} = \begin{cases} Y_t & \text{with prob. } \rho(x^{(t)}, Y_t), \\ x^{(t)} & \text{with prob. } 1 - \rho(x^{(t)}, Y_t), \end{cases}$ where $\rho(x,y) = \min\left\{\frac{f(y)}{f(x)} \frac{q(x|y)}{q(y|x)}, 1\right\}.$

▲□▶ ▲□▶ ▲目▶ ▲目▶ 目 のへの

- The Metropolis-Hastings Algorithm

- Metropolis-Hastings

Features

- Independent of normalizing constants for both f and q(·|x)
 (ie, those constants independent of x)
- Never move to values with f(y) = 0
- ► The chain (x^(t))_t may take the same value several times in a row, even though f is a density wrt Lebesgue measure

• The sequence $(y_t)_t$ is usually **not** a Markov chain

- The Metropolis-Hastings Algorithm

Metropolis-Hastings

Convergence properties

 The M-H Markov chain is reversible, with invariant/stationary density *f* since it satisfies the detailed balance condition

$$f(y) K(y, x) = f(x) K(x, y)$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

Metropolis-Hastings

Convergence properties

 The M-H Markov chain is reversible, with invariant/stationary density *f* since it satisfies the detailed balance condition

$$f(y) K(y, x) = f(x) K(x, y)$$

2. As f is a probability measure, the chain is **positive recurrent**

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

— The Metropolis-Hastings Algorithm

Metropolis-Hastings

Convergence properties

 The M-H Markov chain is reversible, with invariant/stationary density f since it satisfies the detailed balance condition

f(y) K(y, x) = f(x) K(x, y)

As f is a probability measure, the chain is **positive recurrent** If

$$\Pr\left[\frac{f(Y_t) \ q(X^{(t)}|Y_t)}{f(X^{(t)}) \ q(Y_t|X^{(t)})} \ge 1\right] < 1.$$
(1)

that is, the event $\{X^{(t+1)}=X^{(t)}\}$ is possible, then the chain is $\mbox{aperiodic}$

- The Metropolis-Hastings Algorithm

Metropolis-Hastings

Convergence properties (2)

4. If

$$q(y|x) > 0 \text{ for every } (x, y), \tag{2}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

the chain is irreducible

- The Metropolis-Hastings Algorithm

Metropolis-Hastings

Convergence properties (2)

4. If

$$q(y|x) > 0 \text{ for every } (x, y), \tag{2}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

the chain is irreducible

5. For M-H, *f*-irreducibility implies Harris recurrence

— The Metropolis-Hastings Algorithm

Metropolis-Hastings

Convergence properties (2)

4. If

$$q(y|x) > 0 \text{ for every } (x, y), \tag{2}$$

the chain is irreducible

- 5. For M-H, *f*-irreducibility implies **Harris recurrence**
- 6. Thus, for M-H satisfying (1) and (2)

1

(i) For h, with $\mathbb{I}_f |h(X)| < \infty$,

$$\lim_{T \to \infty} \frac{1}{T} \sum_{t=1}^{T} h(X^{(t)}) = \int h(x) df(x) \quad \text{a.e. } f.$$

(ii) and

$$\lim_{n \to \infty} \left\| \int K^n(x, \cdot) \mu(dx) - f \right\|_{TV} = 0$$

for every initial distribution μ , where $K^n(x, \cdot)$ denotes the kernel for n transitions.

Markov Chain Monte Carlo Methods
The Metropolis-Hastings Algorithm
MCMC versions

The Independent Case

The instrumental distribution q is independent of $X^{(t)}$, and is denoted g by analogy with Accept-Reject.

Markov Chain Monte Carlo Methods — The Metropolis-Hastings Algorithm — MCMC versions

The Independent Case

The instrumental distribution q is independent of $X^{(t)}$, and is denoted g by analogy with Accept-Reject.

Algorithm (Independent Metropolis-Hastings)

- Given $x^{(t)}$,
- a Generate $Y_t \sim g(y)$
- b Take

$$X^{(t+1)} = \begin{cases} Y_t & \text{with prob. } \min\left\{\frac{f(Y_t) \ g(x^{(t)})}{f(x^{(t)}) \ g(Y_t)}, 1\right\},\\ x^{(t)} & \text{otherwise.} \end{cases}$$

- The Metropolis-Hastings Algorithm

MCMC versions

Properties

The resulting sample is **not** iid

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

MCMC versions

Properties

The resulting sample is **not** iid but there exist strong convergence properties:

Theorem (Ergodicity)

The algorithm produces a uniformly ergodic chain if there exists a constant ${\cal M}$ such that

$$f(x) \le Mg(x)$$
, $x \in \text{supp } f$.

In this case,

$$\|K^n(x,\cdot) - f\|_{TV} \le \left(1 - \frac{1}{M}\right)^n$$

[Mengersen & Tweedie, 1996]

- The Metropolis-Hastings Algorithm

MCMC versions

Illustration

Example (Noisy AR(1))

Hidden Markov chain from a regular AR(1) model,

$$x_{t+1} = \varphi x_t + \epsilon_{t+1}$$
 $\epsilon_t \sim \mathcal{N}(0, \tau^2)$

and observables

 $y_t | x_t \sim \mathcal{N}(x_t^2, \sigma^2)$

- The Metropolis-Hastings Algorithm

MCMC versions

Illustration

Example (Noisy AR(1))

Hidden Markov chain from a regular AR(1) model,

$$x_{t+1} = \varphi x_t + \epsilon_{t+1} \qquad \epsilon_t \sim \mathcal{N}(0, \tau^2)$$

and observables

$$y_t | x_t \sim \mathcal{N}(x_t^2, \sigma^2)$$

The distribution of x_t given x_{t-1}, x_{t+1} and y_t is

$$\exp\frac{-1}{2\tau^2}\left\{(x_t - \varphi x_{t-1})^2 + (x_{t+1} - \varphi x_t)^2 + \frac{\tau^2}{\sigma^2}(y_t - x_t^2)^2\right\}.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

- The Metropolis-Hastings Algorithm

MCMC versions

Illustration

Example (Noisy AR(1))

Use for proposal the $\mathscr{N}(\mu_t,\omega_t^2)$ distribution, with

$$\mu_t = \varphi \frac{x_{t-1} + x_{t+1}}{1 + \varphi^2} \quad \text{and} \quad \omega_t^2 = \frac{\tau^2}{1 + \varphi^2}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

- The Metropolis-Hastings Algorithm

MCMC versions

Illustration

Example (Noisy AR(1))

Use for proposal the $\mathscr{N}(\mu_t,\omega_t^2)$ distribution, with

$$\mu_t = \varphi \frac{x_{t-1} + x_{t+1}}{1 + \varphi^2} \quad \text{and} \quad \omega_t^2 = \frac{\tau^2}{1 + \varphi^2}$$

Ratio

$$\pi(x)/q_{\rm ind}(x) = \exp{-(y_t - x_t^2)^2/2\sigma^2}$$

is bounded

— The Metropolis-Hastings Algorithm

MCMC versions

Illustration

(top) Last 500 realisations of the chain $\{X_k\}_k$ out of 10,000 iterations; (bottom) histogram of the chain, compared with the target distribution.

— The Metropolis-Hastings Algorithm

MCMC versions

Random walk Metropolis-Hastings

Use of a local perturbation as proposal

 $Y_t = X^{(t)} + \varepsilon_t,$

where $\varepsilon_t \sim g$, independent of $X^{(t)}$.

The instrumental density is now of the form g(y-x) and the Markov chain is a random walk if we take g to be symmetric g(x) = g(-x)

The Metropolis-Hastings Algorithm

MCMC versions

Random walk Metropolis-Hastings

Algorithm (Random walk Metropolis)

Given $x^{(t)}$

1. Generate $Y_t \sim g(y - x^{(t)})$

2. Take

$$X^{(t+1)} = \begin{cases} Y_t & \text{with prob.} \ \min\left\{1, \frac{f(Y_t)}{f(x^{(t)})}\right\},\\ x^{(t)} & \text{otherwise.} \end{cases}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

— The Metropolis-Hastings Algorithm

MCMC versions

Random walk Metropolis-Hastings

Example (Random walk and normal target) Generate $\mathcal{N}(0,1)$ based on the uniform proposal $[-\delta, \delta]$ [Hastings (1970)] The probability of acceptance is then

$$\rho(x^{(t)}, y_t) = \exp\{(x^{(t)^2} - y_t^2)/2\} \wedge 1.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

- The Metropolis-Hastings Algorithm

MCMC versions

Random walk Metropolis-Hastings

Example (Mixture models) $\pi(\theta|x) \propto \prod_{j=1}^{n} \left(\sum_{\ell=1}^{k} p_{\ell} f(x_j|\mu_{\ell}, \sigma_{\ell}) \right) \pi(\theta)$

MCMC versions

Random walk Metropolis-Hastings

Example (Mixture models)

$$\pi(\theta|x) \propto \prod_{j=1}^{n} \left(\sum_{\ell=1}^{k} p_{\ell} f(x_j|\mu_{\ell}, \sigma_{\ell}) \right) \pi(\theta)$$

Metropolis-Hastings proposal:

$$\theta^{(t+1)} = \left\{ \begin{array}{ll} \theta^{(t)} + \omega \varepsilon^{(t)} & \text{if } u^{(t)} < \rho^{(t)} \\ \theta^{(t)} & \text{otherwise} \end{array} \right.$$

where

$$\rho^{(t)} = \frac{\pi(\theta^{(t)} + \omega \varepsilon^{(t)} | x)}{\pi(\theta^{(t)} | x)} \wedge 1$$

and $\boldsymbol{\omega}$ scaled for good acceptance rate

- The Metropolis-Hastings Algorithm

э
- The Metropolis-Hastings Algorithm

MCMC versions

Convergence properties

Uniform ergodicity prohibited by random walk structure

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

— The Metropolis-Hastings Algorithm

MCMC versions

Convergence properties

Uniform ergodicity prohibited by random walk structure At best, geometric ergodicity:

Theorem (Sufficient ergodicity)

For a symmetric density f, log-concave in the tails, and a positive and symmetric density g, the chain $(X^{(t)})$ is geometrically ergodic. [Mengersen & Tweedie, 1996]

▶ no tail effect

— The Metropolis-Hastings Algorithm

└─MCMC versions

Convergence properties

Example (Comparison of tail effects)

Random-walk

Metropolis–Hastings algorithms based on a $\mathcal{N}(0,1)$ instrumental for the generation of (a) a $\mathcal{N}(0,1)$ distribution and (b) a distribution with density $\psi(x) \propto (1+|x|)^{-3}$

parallel independent chains

— The Metropolis-Hastings Algorithm

MCMC versions

Convergence properties

Example (Cauchy by normal) Cauchy $\mathscr{C}(0,1)$ target and Gaussian random walk proposal, $\xi' \sim \mathscr{N}(\xi, \sigma^2)$, with acceptance probability

$$\frac{1+\xi^2}{1+(\xi')^2} \wedge 1 \,,$$

Overall fit of the Cauchy density by the histogram satisfactory, but poor exploration of the tails: 99% quantile of $\mathscr{C}(0,1)$ equal to 3, but no simulation exceeds 14 out of 10,000!

[Roberts & Tweedie, 2004]

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

Markov Chain Monte Carlo Methods The Metropolis-Hastings Algorithm MCMC versions

MCMC versions

Convergence properties

Range of 500 parallel runs for the same setup

Markov Chain Monte Carlo Methods The Metropolis-Hastings Algorithm MCMC versions

Comments

- [CLT, Rosenthal's inequality...] *h*-ergodicity implies CLT for additive (possibly unbounded) functionals of the chain, Rosenthal's inequality and so on...
- ► [Control of the moments of the return-time] The condition implies (because h ≥ 1) that

$$\sup_{x \in C} \mathbb{E}_x[r_0(\tau_C)] \le \sup_{x \in C} \mathbb{E}_x \left\{ \sum_{k=0}^{\tau_C - 1} r(k) h(X_k) \right\} < \infty,$$

where $r_0(n) = \sum_{l=0}^{n} r(l)$ Can be used to derive bounds for the coupling time, an essential step to determine computable bounds, using coupling inequalities

[Roberts & Tweedie, 1998; Fort & Moulines, 2000]

— The Metropolis-Hastings Algorithm

Extensions

Extensions

There are many other families of HM algorithms

• Adaptive Rejection Metropolis Sampling

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

- Reversible Jump (later!)
- Langevin algorithms
- not HMC (different H!)

to name just a few...

Markov Chain Monte Carlo Methods The Metropolis-Hastings Algorithm Extensions

Langevin Algorithms

Proposal based on the Langevin diffusion L_t is defined by the stochastic differential equation

$$dL_t = dB_t + \frac{1}{2}\nabla \log f(L_t)dt,$$

where B_t is the standard Brownian motion

Theorem

The Langevin diffusion is the only non-explosive diffusion which is reversible with respect to $f. \end{tabular}$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

- The Metropolis-Hastings Algorithm

Extensions

Discretization

Instead, consider the sequence

$$x^{(t+1)} = x^{(t)} + \frac{\sigma^2}{2} \nabla \log f(x^{(t)}) + \sigma \varepsilon_t, \qquad \varepsilon_t \sim \mathcal{N}_p(0, I_p)$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

where σ^2 corresponds to the discretization step

— The Metropolis-Hastings Algorithm

- Extensions

Discretization

Instead, consider the sequence

$$x^{(t+1)} = x^{(t)} + \frac{\sigma^2}{2} \nabla \log f(x^{(t)}) + \sigma \varepsilon_t, \qquad \varepsilon_t \sim \mathcal{N}_p(0, I_p)$$

where σ^2 corresponds to the discretization step Unfortunately, the discretized chain may be transient, for instance when

$$\lim_{x \to \pm \infty} \left| \sigma^2 \nabla \log f(x) |x|^{-1} \right| > 1$$

Markov Chain Monte Carlo Methods
The Metropolis-Hastings Algorithm
Extensions

MH correction (MALA)

Accept the new value Y_t with probability

$$\frac{f(Y_t)}{f(x^{(t)})} \cdot \frac{\exp\left\{-\left\|Y_t - x^{(t)} - \frac{\sigma^2}{2}\nabla\log f(x^{(t)})\right\|^2 / 2\sigma^2\right\}}{\exp\left\{-\left\|x^{(t)} - Y_t - \frac{\sigma^2}{2}\nabla\log f(Y_t)\right\|^2 / 2\sigma^2\right\}} \wedge 1.$$

Choice of the scaling factor σ

Should lead to an acceptance rate of 0.574 to achieve optimal convergence rates (when the components of x are uncorrelated) [Roberts & Rosenthal, 1998]

The Metropolis-Hastings Algorithm

- Extensions

Optimizing the Acceptance Rate

Problem of choice of the transition kernel from a practical point of view

Most common alternatives:

(a) a fully automated algorithm like ARMS;

[Gilks and Wild, 1992]

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

(b) an instrumental density g which approximates f, such that f/g is bounded for uniform ergodicity to apply;

(c) a random walk

In both cases (b) and (c), the choice of g is critical,

The Metropolis-Hastings Algorithm

Extensions

Optimizing the Acceptance Rate

Example (Noisy AR(1))

For a Gaussian random walk with scale ω small enough, the random walk never jumps to the other mode. But if the scale ω is sufficiently large, the Markov chain explores both modes and give a satisfactory approximation of the target distribution.

Rao-Blackwellisation

True Metropolis-Hastings sequence

Alternative representation of Metropolis–Hastings estimator δ as

$$\delta = \frac{1}{n} \sum_{t=1}^{n} h(x^{(t)}) = \frac{1}{n} \sum_{i=1}^{M_n} \mathfrak{n}_i h(\mathfrak{z}_i) \,,$$

where

- ▶ 𝔅_i's are the accepted 𝒱_j's,
- ▶ M_n is the number of accepted y_j 's till time n,
- \mathfrak{n}_i is the number of times \mathfrak{z}_i appears in the sequence $(x^{(t)})_t$.

- The Metropolis-Hastings Algorithm

Rao-Blackwellisation

The "accepted candidates"

Define

$$\tilde{q}(\cdot|\mathbf{z}_i) = \frac{\alpha(\mathbf{z}_i, \cdot) \, q(\cdot|\mathbf{z}_i)}{p(\mathbf{z}_i)} \le \frac{q(\cdot|\mathbf{z}_i)}{p(\mathbf{z}_i)}$$

where $p(\mathfrak{z}_i) = \int \alpha(\mathfrak{z}_i, y) q(y|\mathfrak{z}_i) dy$ To simulate from $\tilde{q}(\cdot|\mathfrak{z}_i)$

- 1. Propose a candidate $y \sim q(\cdot|\mathfrak{z}_i)$
- 2. Accept with probability

$$\tilde{q}(y|\mathfrak{z}_i) \left/ \left(\frac{q(y|\mathfrak{z}_i)}{p(\mathfrak{z}_i)} \right) = \alpha(\mathfrak{z}_i, y)$$

Otherwise, reject it and starts again.

- The Metropolis-Hastings Algorithm

Rao-Blackwellisation

The "accepted candidates"

Importance sampling perspective

1. A natural idea:

$$\delta^* \simeq \frac{\sum_{i=1}^{M_n} \frac{h(\mathfrak{z}_i)}{p(\mathfrak{z}_i)}}{\sum_{i=1}^{M_n} \frac{1}{p(\mathfrak{z}_i)}} = \frac{\sum_{i=1}^{M_n} \frac{\pi(\mathfrak{z}_i)}{\tilde{\pi}(\mathfrak{z}_i)} h(\mathfrak{z}_i)}{\sum_{i=1}^{M_n} \frac{\pi(\mathfrak{z}_i)}{\tilde{\pi}(\mathfrak{z}_i)}}.$$

2. But p not available in closed form.

— The Metropolis-Hastings Algorithm

Rao-Blackwellisation

Importance sampling perspective

1. A natural idea:

$$\delta^* \simeq \frac{\sum_{i=1}^{M_n} \frac{h(\mathfrak{z}_i)}{p(\mathfrak{z}_i)}}{\sum_{i=1}^{M_n} \frac{1}{p(\mathfrak{z}_i)}} = \frac{\sum_{i=1}^{M_n} \frac{\pi(\mathfrak{z}_i)}{\tilde{\pi}(\mathfrak{z}_i)} h(\mathfrak{z}_i)}{\sum_{i=1}^{M_n} \frac{\pi(\mathfrak{z}_i)}{\tilde{\pi}(\mathfrak{z}_i)}}.$$

- 2. But p not available in closed form.
- 3. The geometric \mathfrak{n}_i is the replacement, an obvious solution that is used in the original Metropolis–Hastings estimate since $\mathbb{E}[\mathfrak{n}_i] = 1/p(\mathfrak{z}_i).$

— The Metropolis-Hastings Algorithm

Rao–Blackwellisation

The Bernoulli factory

The crude estimate of $1/p(\mathfrak{z}_i)$,

$$\mathfrak{n}_i = 1 + \sum_{j=1}^{\infty} \prod_{\ell \le j} \mathbb{I} \left\{ u_\ell \ge \alpha(\mathfrak{z}_i, y_\ell) \right\} \,,$$

can be improved:

Lemma (Douc & X., 2011)

If $(y_j)_j$ is an iid sequence with distribution $q(y|\mathfrak{z}_i)$, the quantity

$$\hat{\xi}_i = 1 + \sum_{j=1}^{\infty} \prod_{\ell \le j} \{1 - \alpha(\mathfrak{z}_i, y_\ell)\}$$

is an unbiased estimator of $1/p(\mathfrak{z}_i)$ which variance, conditional on \mathfrak{z}_i , is lower than the conditional variance of \mathfrak{n}_i , $\{1 - p(\mathfrak{z}_i)\}/p^2(\mathfrak{z}_i)$.

- The Metropolis-Hastings Algorithm

Rao-Blackwellisation

Rao-Blackwellised, for sure?

$$\hat{\xi}_i = 1 + \sum_{j=1}^{\infty} \prod_{\ell \le j} \{1 - \alpha(\mathfrak{z}_i, y_\ell)\}\$$

1. Infinite sum but finite with at least positive probability:

$$\alpha(x^{(t)}, y_t) = \min\left\{1, \frac{\pi(y_t)}{\pi(x^{(t)})} \frac{q(x^{(t)}|y_t)}{q(y_t|x^{(t)})}\right\}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

For example: take a symmetric random walk as a proposal. 2. What if we wish to be sure that the sum is finite?

- The Metropolis-Hastings Algorithm

Rao-Blackwellisation

Rao-Blackwellised, for sure?

$$\hat{\xi}_i = 1 + \sum_{j=1}^{\infty} \prod_{\ell \le j} \{1 - \alpha(\mathfrak{z}_i, y_\ell)\}$$

1. Infinite sum but finite with at least positive probability:

$$\alpha(x^{(t)}, y_t) = \min\left\{1, \frac{\pi(y_t)}{\pi(x^{(t)})} \frac{q(x^{(t)}|y_t)}{q(y_t|x^{(t)})}\right\}$$

For example: take a symmetric random walk as a proposal. 2. What if we wish to be sure that the sum is finite? Finite horizon k version:

$$\hat{\xi}_i^k = 1 + \sum_{j=1}^{\infty} \prod_{1 \le \ell \le k \land j} \left\{ 1 - \alpha(\mathfrak{z}_i, y_j) \right\} \prod_{k+1 \le \ell \le j} \mathbb{I} \left\{ u_\ell \ge \alpha(\mathfrak{z}_i, y_\ell) \right\}$$

— The Metropolis-Hastings Algorithm

Rao-Blackwellisation

Variance improvement

Theorem (Douc & X., 2011)

If $(y_j)_j$ is an iid sequence with distribution $q(y|\mathfrak{z}_i)$ and $(u_j)_j$ is an iid uniform sequence, for any $k \ge 0$, the quantity

$$\hat{\xi}_i^k = 1 + \sum_{j=1}^{\infty} \prod_{1 \le \ell \le k \land j} \left\{ 1 - \alpha(\mathfrak{z}_i, y_j) \right\} \prod_{k+1 \le \ell \le j} \mathbb{I} \left\{ u_\ell \ge \alpha(\mathfrak{z}_i, y_\ell) \right\}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

is an unbiased estimator of $1/p(\mathfrak{z}_i)$ with an almost sure finite number of terms.

— The Metropolis-Hastings Algorithm

Rao-Blackwellisation

Variance improvement

Theorem (Douc & X., 2011)

If $(y_j)_j$ is an iid sequence with distribution $q(y|\mathfrak{z}_i)$ and $(u_j)_j$ is an iid uniform sequence, for any $k \ge 0$, the quantity

$$\hat{\xi}_i^k = 1 + \sum_{j=1}^{\infty} \prod_{1 \le \ell \le k \land j} \left\{ 1 - \alpha(\mathfrak{z}_i, y_j) \right\} \prod_{k+1 \le \ell \le j} \mathbb{I} \left\{ u_\ell \ge \alpha(\mathfrak{z}_i, y_\ell) \right\}$$

is an unbiased estimator of $1/p(\mathfrak{z}_i)$ with an almost sure finite number of terms. Moreover, for $k \ge 1$,

$$\mathbb{V}\hat{\xi}_{i}^{k}\mathfrak{z}_{i} = \frac{1-p(\mathfrak{z}_{i})}{p^{2}(\mathfrak{z}_{i})} - \frac{1-(1-2p(\mathfrak{z}_{i})+r(\mathfrak{z}_{i}))^{k}}{2p(\mathfrak{z}_{i})-r(\mathfrak{z}_{i})} \left(\frac{2-p(\mathfrak{z}_{i})}{p^{2}(\mathfrak{z}_{i})}\right) \left(p(\mathfrak{z}_{i})-r(\mathfrak{z}_{i})\right),$$

where $p(\mathfrak{z}_i) := \int \alpha(\mathfrak{z}_i, y) \, q(y|\mathfrak{z}_i) \, dy$. and $r(\mathfrak{z}_i) := \int \alpha^2(\mathfrak{z}_i, y) \, q(y|\mathfrak{z}_i) \, dy$.

— The Metropolis-Hastings Algorithm

Rao-Blackwellisation

Variance improvement

Theorem (Douc & X., 2011)

If $(y_j)_j$ is an iid sequence with distribution $q(y|\mathfrak{z}_i)$ and $(u_j)_j$ is an iid uniform sequence, for any $k \ge 0$, the quantity

$$\hat{\xi}_i^k = 1 + \sum_{j=1}^{\infty} \prod_{1 \le \ell \le k \land j} \left\{ 1 - \alpha(\mathfrak{z}_i, y_j) \right\} \prod_{k+1 \le \ell \le j} \mathbb{I} \left\{ u_\ell \ge \alpha(\mathfrak{z}_i, y_\ell) \right\}$$

is an unbiased estimator of $1/p(\mathfrak{z}_i)$ with an almost sure finite number of terms. Therefore, we have

$$\mathbb{V}\hat{\xi}_{i}\mathfrak{z}_{i} \leq \mathbb{V}\hat{\xi}_{i}^{k}\mathfrak{z}_{i} \leq \mathbb{V}\hat{\xi}_{i}^{0}\mathfrak{z}_{i} = \mathbb{V}\mathfrak{n}_{i}\mathfrak{z}_{i}$$
 .

The Metropolis-Hastings Algorithm

Delayed acceptance

The "Big Data" plague

Simulation from posterior with large sample size n

- Computing time at least of order O(n)
- solutions using likelihood decomposition

$$\prod_{i=1}^n \ell(\theta|x_i)$$

and handling subsets on different processors (CPU), graphical units (GPU), or computers

[Scott et al., 2013, Korattikara et al., 2013]

 no consensus on method of choice, with instabilities from removing most prior input and uncalibrated approximations [Neiswanger et al., 2013]
- The Metropolis-Hastings Algorithm

Delayed acceptance

Proposed solution

"There is no problem an absence of decision cannot solve." Anon.

Given $\alpha(x,y) := 1 \wedge r(x,y)$, factorise

$$r(x,y) = \prod_{k=1}^{d} \rho_k(x,y)$$

under constraint $\rho_k(x, y) = \rho_k(y, x)^{-1}$ Delayed Acceptance Markov kernel given by

$$\tilde{P}(x,A) := \int_{A} q(x,y)\tilde{\alpha}(x,y)\mathrm{d}y + \left(1 - \int_{\mathsf{X}} q(x,y)\tilde{\alpha}(x,y)\mathrm{d}y\right)\mathbf{1}_{A}(x)$$

where

$$\tilde{\alpha}(x,y) := \prod_{k=1}^{d} \{1 \land \rho_k(x,y)\}.$$

— The Metropolis-Hastings Algorithm

Delayed acceptance

Proposed solution

Algorithm 1 Delayed Acceptance

To sample from $\tilde{P}(x, \cdot)$:

- 1. Sample $y \sim Q(x, \cdot)$.
- 2. For k = 1, ..., d:
 - with probability $1 \wedge \rho_k(x, y)$ continue
 - \blacktriangleright otherwise stop and output x

3. Output y

Arrange terms in product so that most computationally intensive ones calculated 'at the end' hence least often

— The Metropolis-Hastings Algorithm

Delayed acceptance

Proposed solution

Algorithm 1 Delayed Acceptance

To sample from $\tilde{P}(x, \cdot)$:

- 1. Sample $y \sim Q(x, \cdot)$.
- 2. For k = 1, ..., d:
 - with probability $1 \wedge \rho_k(x, y)$ continue
 - \blacktriangleright otherwise stop and output x

3. Output y

Generalization of Fox & Nicholls (1997) and Christen & Fox (2005), where testing for acceptance with approximation before computing exact likelihood first suggested

— The Metropolis-Hastings Algorithm

Delayed acceptance

The "Big Data" plague

Delayed Acceptance intended for likelihoods or priors, but not a clear solution for "Big Data" problems

- 1. all product terms must be computed
- 2. all terms previously computed either stored for future comparison or recomputed
- 3. sequential approach limits parallel gains...
- 4. ...unless prefetching scheme added to delays

[Strid (2010)]

Adaptive MCMC

Illustration

Example (Poly t distribution)

Consider a *t*-distribution $\mathcal{T}(3, \theta, 1)$ sample (x_1, \ldots, x_n) with a flat prior $\pi(\theta) = 1$ If we try fit a normal proposal from empirical mean and variance of the chain so far,

$$\mu_t = rac{1}{t} \sum_{i=1}^t heta^{(i)}$$
 and $\sigma_t^2 = rac{1}{t} \sum_{i=1}^t (heta^{(i)} - \mu_t)^2$

Adaptive MCMC

Illustration

Example (Poly *t* distribution)

Consider a *t*-distribution $\mathcal{T}(3, \theta, 1)$ sample (x_1, \ldots, x_n) with a flat prior $\pi(\theta) = 1$ If we try fit a normal proposal from empirical mean and variance of the chain so far,

$$\mu_t = rac{1}{t} \sum_{i=1}^t heta^{(i)}$$
 and $\sigma_t^2 = rac{1}{t} \sum_{i=1}^t (heta^{(i)} - \mu_t)^2$

Metropolis-Hastings algorithm with acceptance probability

$$\prod_{j=2}^{n} \left[\frac{\nu + (x_j - \theta^{(t)})^2}{\nu + (x_j - \xi)^2} \right]^{-(\nu+1)/2} \frac{\exp{-(\mu_t - \theta^{(t)})^2/2\sigma_t^2}}{\exp{-(\mu_t - \xi)^2/2\sigma_t^2}},$$

where $\xi \sim \mathcal{N}(\mu_t, \sigma_t^2)$.

— The Metropolis-Hastings Algorithm

Adaptive MCMC

Illustration

Example (Poly t distribution (2))

Invalid scheme:

- when range of initial values too small, the θ⁽ⁱ⁾'s cannot converge to the target distribution and concentrates on too small a support.
- long-range dependence on past values modifies the distribution of the sequence.
- using past simulations to create a non-parametric approximation to the target distribution does not work either

- The Metropolis-Hastings Algorithm

Adaptive MCMC

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

Gibbs Sampling

General Principles

Properties

The full conditionals densities f_1, \ldots, f_p are the only densities used for simulation. Thus, even in a high dimensional problem, all of the simulations may be univariate

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

Gibbs Sampling

General Principles

Properties

The full conditionals densities f_1, \ldots, f_p are the only densities used for simulation. Thus, even in a high dimensional problem, all of the simulations may be univariate The Gibbs sampler is not reversible with respect to f. However, each of its p components is. Besides, it can be turned into a reversible sampler, either using the *Random Scan Gibbs sampler* or running instead the (double) sequence

 $f_1 \cdots f_{p-1} f_p f_{p-1} \cdots f_1$

Gibbs Sampling

General Principles

A Very Simple Example: Independent $\mathcal{N}(\mu, \sigma^2)$ Observations

When $Y_1, \ldots, Y_n \stackrel{\text{iid}}{\sim} \mathcal{N}(y|\mu, \sigma^2)$ with both μ and σ unknown, the posterior in (μ, σ^2) is conjugate outside a standard family

Gibbs Sampling

General Principles

A Very Simple Example: Independent $\mathcal{N}(\mu, \sigma^2)$ Observations

When $Y_1, \ldots, Y_n \stackrel{\text{iid}}{\sim} \mathcal{N}(y|\mu, \sigma^2)$ with both μ and σ unknown, the posterior in (μ, σ^2) is conjugate outside a standard family

But...

$$\mu | \mathbf{Y}_{0:n}, \sigma^2 \sim \mathcal{N} \left(\mu \left| \frac{1}{n} \sum_{i=1}^n Y_i, \frac{\sigma^2}{n} \right. \right) \\ \sigma^2 | \mathbf{Y}_{1:n}, \mu \sim \mathcal{IG} \left(\sigma^2 \left| \frac{n}{2} - 1, \frac{1}{2} \sum_{i=1}^n (Y_i - \mu)^2 \right. \right)$$

assuming constant (improper) priors on both μ and σ^2

 \blacktriangleright Hence we may use the Gibbs sampler for simulating from the posterior of (μ,σ^2)

Gibbs Sampling

General Principles

A Very Simple Example: Independent $\mathcal{N}(\mu, \sigma^2)$ Observations

```
R Gibbs Sampler for Gaussian posterior

n = length(Y);

S = sum(Y);

mu = S/n;

for (i in 1:500)

S2 = sum((Y-mu)^2);

sigma2 = 1/rgamma(1,n/2-1,S2/2);

mu = S/n + sqrt(sigma2/n)*rnorm(1);

Gibbs Sampling

└─ Convergence

Properties of the Gibbs sampler

Theorem (Convergence)

For

$$(Y_1, Y_2, \cdots, Y_p) \sim g(y_1, \ldots, y_p),$$

if either

[Positivity condition]

(i) $g^{(i)}(y_i) > 0$ for every $i = 1, \dots, p$, implies that $g(y_1, \dots, y_p) > 0$, where $g^{(i)}$ denotes the marginal distribution of Y_i , or

(*ii*) the transition kernel is absolutely continuous with respect to g, then the chain is irreducible and positive Harris recurrent.

Gibbs Sampling

- Convergence

Properties of the Gibbs sampler (2)

Consequences

(i) If $\int h(y)g(y)dy < \infty$, then

$$\lim_{nT\to\infty} \frac{1}{T} \sum_{t=1}^T h_1(Y^{(t)}) = \int h(y)g(y)dy \text{ a.e. } g.$$

(ii) If, in addition, $(Y^{(t)})$ is aperiodic, then

$$\lim_{n \to \infty} \left\| \int K^n(y, \cdot) \mu(dx) - f \right\|_{TV} = 0$$

for every initial distribution μ .

Gibbs Sampling

Convergence

Slice sampler

fast on that slice

For convergence, the properties of X_t and of $f(X_t)$ are identical

Theorem (Uniform ergodicity)

If f is bounded and $\operatorname{supp} f$ is bounded, the simple slice sampler is uniformly ergodic.

General HC decomposition

Under the positivity condition, the joint distribution g satisfies

$$g(y_1, \dots, y_p) \propto \prod_{j=1}^p \frac{g_{\ell_j}(y_{\ell_j}|y_{\ell_1}, \dots, y_{\ell_{j-1}}, y'_{\ell_{j+1}}, \dots, y'_{\ell_p})}{g_{\ell_j}(y'_{\ell_j}|y_{\ell_1}, \dots, y_{\ell_{j-1}}, y'_{\ell_{j+1}}, \dots, y'_{\ell_p})}$$

for every permutation ℓ on $\{1, 2, \dots, p\}$ and every $y' \in \mathscr{Y}$.

Gibbs Sampling

The Hammersley-Clifford theorem

Rao-Blackwellization

If $(y_1, y_2, \ldots, y_p)^{(t)}, t = 1, 2, \ldots T$ is the output from a Gibbs sampler

$$\delta_0 = \frac{1}{T} \sum_{t=1}^T h\left(y_1^{(t)}\right) \to \int h(y_1)g(y_1)dy_1$$

and is unbiased.

Gibbs Sampling

The Hammersley-Clifford theorem

Rao-Blackwellization

If $(y_1, y_2, \ldots, y_p)^{(t)}, t = 1, 2, \ldots T$ is the output from a Gibbs sampler

$$\delta_0 = \frac{1}{T} \sum_{t=1}^T h\left(y_1^{(t)}\right) \to \int h(y_1)g(y_1)dy_1$$

and is unbiased.

The Rao-Blackwellization replaces δ_0 with its conditional expectation

$$\delta_{rb} = \frac{1}{T} \sum_{t=1}^{T} \mathbb{I} \left[h(Y_1) | y_2^{(t)}, \dots, y_p^{(t)} \right]$$

Gibbs Sampling

The Hammersley-Clifford theorem

Rao-Blackwellization (2)

Improper priors

 \oint Unsuspected danger resulting from careless use of MCMC algorithms:

It may happen that

- o all conditional distributions are well defined,
- all conditional distributions may be simulated from, but...
- the system of conditional distributions may not correspond to any joint distribution

Warning The problem is due to careless use of the Gibbs sampler in a situation for which the underlying assumptions are violated

Gibbs Sampling

Improper Priors

Improper posteriors

Example (Conditional exponential distributions) For the model

$$X_1|x_2 \sim \mathscr{E}xp(x_2), \quad X_2|x_1 \sim \mathscr{E}xp(x_1)$$

the only candidate $f(x_1, x_2)$ for the joint density is

 $f(x_1, x_2) \propto \exp(-x_1 x_2),$

but

$$\int f(x_1, x_2) dx_1 dx_2 = \infty$$

© These conditionals do not correspond to a joint probability distribution

Gibbs Sampling

Improper Priors

Improper posteriors

Example (Improper random effects) Consider

$$Y_{ij} = \mu + \alpha_i + \varepsilon_{ij}, \quad i = 1, \dots, I, \ j = 1, \dots, J,$$

where

$$\alpha_i \sim \mathcal{N}(0, \sigma^2)$$
 and $\varepsilon_{ij} \sim \mathcal{N}(0, \tau^2)$,

the Jeffreys (improper) prior for the parameters $\mu,\,\sigma$ and τ is

$$\pi(\mu, \sigma^2, \tau^2) = \frac{1}{\sigma^2 \tau^2} \; .$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Gibbs Sampling

Improper Priors

Improper posteriors

Example (Improper random effects 2) The conditional distributions

$$\begin{split} &\alpha_{i}|y,\mu,\sigma^{2},\tau^{2} ~\sim ~\mathcal{N}\left(\frac{J(\bar{y}_{i}-\mu)}{J+\tau^{2}\sigma^{-2}},(J\tau^{-2}+\sigma^{-2})^{-1}\right) ,\\ &\mu|\alpha,y,\sigma^{2},\tau^{2} ~\sim ~\mathcal{N}(\bar{y}-\bar{\alpha},\tau^{2}/JI) ,\\ &\sigma^{2}|\alpha,\mu,y,\tau^{2} ~\sim ~\mathcal{IG}\left(I/2,(1/2)\sum_{i}\alpha_{i}^{2}\right) ,\\ &\tau^{2}|\alpha,\mu,y,\sigma^{2} ~\sim ~\mathcal{IG}\left(IJ/2,(1/2)\sum_{i,j}(y_{ij}-\alpha_{i}-\mu)^{2}\right) , \end{split}$$

are well-defined and a Gibbs sampler can be easily implemented in this setting.

Gibbs Sampling

Improper Priors

Improper posteriors

Example (Improper random effects 2)

The figure shows the sequence of $\mu^{(t)}$'s and its histogram over 1,000 iterations. They both fail to indicate that the corresponding "joint distribution" does not exist
Gibbs Sampling

Gibbs Sampling

Improper Priors

Final notes on impropriety

The improper posterior Markov chain cannot be positive recurrent

The major task in such settings is to find indicators that flag that something is wrong. However, the output of an "improper" Gibbs sampler may not differ from a positive recurrent Markov chain.

Gibbs Sampling

Improper Priors

Final notes on impropriety

The improper posterior Markov chain cannot be positive recurrent

The major task in such settings is to find indicators that flag that something is wrong. However, the output of an "improper" Gibbs sampler may not differ from a positive recurrent Markov chain.

Example

The random effects model was initially treated in Gelfand & al (1990) as a legitimate model

Hamiltonian Monte Carlo

The Metropolis-Hastings Algorithm

Gibbs Sampling

Hamiltonian Monte Carlo

Piecewise Deterministic Versions

Hamiltonian (or hybrid) Monte Carlo (HMC) auxiliary variable technique that takes advantage of a continuous time Markov process to sample from target $\pi(\theta)$

Auxiliary variable $\vartheta \in \mathbb{R}^d$ introduced along with a density $\varpi(\vartheta|\theta)$ so that the joint distribution of (θ, ϑ) enjoys $\pi(\theta)$ as its marginal

$$\pi(\theta) = \int \pi(\theta) \varpi(\vartheta|\theta) \mathsf{d}\vartheta$$

Based on representation of joint distribution

 $\omega(\theta, \vartheta) = \pi(\theta) \varpi(\vartheta|\theta) \propto \exp\{-H(\theta, \vartheta)\},\,$

where $H(\cdot)$ called *Hamiltonian*

Based on representation of joint distribution

$$\omega(\theta, \vartheta) = \pi(\theta) \varpi(\vartheta|\theta) \propto \exp\{-H(\theta, \vartheta)\}\,,$$

where $H(\cdot)$ called Hamiltonian Hamiltonian Monte Carlo (HMC) associated with the continuous time process (θ_t,ϑ_t) generated by the so-called Hamiltonian equations

$$\frac{\mathrm{d}\theta_t}{\mathrm{d}t} = \frac{\partial H}{\partial \vartheta}(\theta_t, \vartheta_t) \qquad \frac{\mathrm{d}\vartheta_t}{\mathrm{d}t} = -\frac{\partial H}{\partial \theta}(\theta_t, \vartheta_t) \,,$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Based on representation of joint distribution

 $\omega(\theta, \vartheta) = \pi(\theta) \varpi(\vartheta|\theta) \propto \exp\{-H(\theta, \vartheta)\},\$

where $H(\cdot)$ called Hamiltonian Keep Hamiltonian target stable over time, as

$$\frac{\mathrm{d}H(\theta_t,\vartheta_t)}{\mathrm{d}t} = \frac{\partial H}{\partial\vartheta}(\theta_t,\vartheta_t) \frac{\mathrm{d}\vartheta_t}{\mathrm{d}t} + \frac{\partial H}{\partial\theta}(\theta_t,\vartheta_t) \frac{\mathrm{d}\theta_t}{\mathrm{d}t} = 0$$

Background

Approach from physics (Duane et al., 1987) popularised in statistics by Neal (1996, 2002)

Background

- Above continuous time Markov process is deterministic
- Only explores single given level set

$$\left\{ (\theta, \vartheta) : H(\theta, \vartheta) = H(\theta_0, \vartheta_0) \right\},\$$

instead of the whole augmented state space $\mathbb{R}^{2\times d}$

- Meaning lack of irreducibility
- Solution out is to refresh momentum,

$$\vartheta_t \sim \varpi(\vartheta|\theta_{t-})$$

at random times au_n with $\{ au_n - au_{n-1}\}$ exponential variates

 Specific piecewise deterministic Markov process using Hamiltonian dynamics

Practical implementation

Free conditional density $\varpi(\vartheta|\theta)$, usually chosen as Gaussian with either a constant covariance matrix M corresponding to target covariance or as local curvature depending on θ in Riemannian and Lagrangian HMC (Girolami and Calderhead, 2011; Lan et al., 2016)

For fixed covariance matrix M, Hamiltonian equations

$$\frac{\mathrm{d}\theta_t}{\mathrm{d}t} = M^{-1}\vartheta_t \qquad \frac{\mathrm{d}\vartheta_t}{\mathrm{d}t} = \nabla \mathcal{L}(\theta_t)\,,$$

equal to the score function

Practical implementation

For fixed covariance matrix M, Hamiltonian equations

$$\frac{\mathrm{d}\theta_t}{\mathrm{d}t} = M^{-1}\vartheta_t \qquad \frac{\mathrm{d}\vartheta_t}{\mathrm{d}t} = \nabla\mathcal{L}(\theta_t)\,,$$

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ □ のへぐ

equal to the score function

Discretisation simulation technique: symplectic integrator

One version in the independent case with constant covariance ${\cal M}$ made of leapfrog steps

$$\begin{split} \vartheta_{t+\epsilon/2} &= \vartheta_t + \epsilon \nabla \mathcal{L}(\theta_t)/2, \\ \theta_{t+\epsilon} &= \theta_t + \epsilon M^{-1} \vartheta_{t+\epsilon/2}, \\ \vartheta_{t+\epsilon} &= \vartheta_{t+\epsilon/2} + \epsilon \nabla \mathcal{L}(\theta_{t+\epsilon})/2, \end{split}$$

where ϵ is time-discretisation step Using proposal on ϑ_0 drawn from Gaussian auxiliary target and deciding on acceptance of the value of $(\theta_{T\epsilon}, \vartheta_{T\epsilon})$ by a Metropolis–Hastings step

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

One version in the independent case with constant covariance ${\cal M}$ made of leapfrog steps

$$\begin{split} \vartheta_{t+\epsilon/2} &= \vartheta_t + \epsilon \nabla \mathcal{L}(\theta_t)/2, \\ \theta_{t+\epsilon} &= \theta_t + \epsilon M^{-1} \vartheta_{t+\epsilon/2}, \\ \vartheta_{t+\epsilon} &= \vartheta_{t+\epsilon/2} + \epsilon \nabla \mathcal{L}(\theta_{t+\epsilon})/2, \end{split}$$

where ϵ is time-discretisation step Note that first two leapfrog steps induce a Langevin move on θ_t :

$$\theta_{t+\epsilon} = \theta_t + \epsilon^2 M^{-1} \nabla \mathcal{L}(\theta_t) / 2 + \epsilon M^{-1} \vartheta_t \,,$$

One version in the independent case with constant covariance ${\cal M}$ made of leapfrog steps

$$\begin{split} \vartheta_{t+\epsilon/2} &= \vartheta_t + \epsilon \nabla \mathcal{L}(\theta_t)/2, \\ \theta_{t+\epsilon} &= \theta_t + \epsilon M^{-1} \vartheta_{t+\epsilon/2}, \\ \vartheta_{t+\epsilon} &= \vartheta_{t+\epsilon/2} + \epsilon \nabla \mathcal{L}(\theta_{t+\epsilon})/2, \end{split}$$

where ϵ is time-discretisation step Discretising Hamiltonian dynamics introduces two free parameters, step size ϵ and trajectory length $T\epsilon$, both to be calibrated.

no U turns

- empirically successful and popular version of HMC: "no-U-turn sampler" (NUTS) adapts value of
 e based on primal-dual averaging
- and eliminates need to choose trajectory length T via a recursive algorithm that builds a set of candidate proposals for a number of forward and backward leapfrog steps, stopping automatically when simulated path traces back

Marketing arguments

Current default workhorse: reversible MCMC methods

Non-reversible MCMC algorithms based on piecewise deterministic Markov processes perform well empirically

Motivations

Marketing arguments

Non-reversible MCMC algorithms based on piecewise deterministic Markov processes perform well empirically Quantitative convergence rates and variance now available

- ► Physics (Peters & De With, 2012; Krauth et al., 2009, 2015, 2016) roots
- Mesquita and Hespanha (2010) show geometric ergodicity for exponentially decaying tail targets
- ▶ Monmarch (2016) gives sharp results for compact state-spaces
- Bierkens et al. (2016a,b) show ergodicity targets on the real line

Motivation: piecewise deterministic Markov process

PDMP sampler is a (new?) continuous-time, non-reversible MCMC method based on auxiliary variables

1. particle physics simulation

[Peters et al., 2012]

2. empirically state-of-the-art performances

[Bouchard et al., 2017]

3. exact subsampled in big data

[Bierkens et al., 2017]

4. geometric ergodicity for a large class of distribution

[Deligiannidis et al., 2017, Bierkens et al., 2017]

5. Ability to deal with intractable potential $U(x) = \int U_{\omega}(x)\mu(d\omega)$ [Pakman et al., 2016]

Older versions

Use of alternative methodology based on Birth–&-Death (point) process

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Older versions

Use of alternative methodology based on Birth–&-Death (point) process

Idea: Create Markov chain in *continuous time*, i.e. a *Markov jump process*

Time till next modification (jump) exponentially distributed with intensity $q(\theta, \theta')$ depending on current and future states. [Preston, 1976; Ripley, 1977; Geyer & Møller, 1994; Stevens, 1999]

Older versions

Difference with MH-MCMC: Whenever jump occurs, corresponding move *always accepted*. Acceptance probabilities replaced with holding times.

Implausible configurations

 $L(\theta)\pi(\theta)\ll 1$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

die quickly.

Older versions

Difference with MH-MCMC: Whenever jump occurs, corresponding move *always accepted*. Acceptance probabilities replaced with holding times.

Implausible configurations

 $L(\theta)\pi(\theta)\ll 1$

die quickly. Sufficient to have detailed balance

 $L(\theta)\pi(\theta)q(\theta,\theta') = L(\theta')\pi(\theta')q(\theta',\theta) \quad \text{for all } \theta,\theta'$

for $\tilde{\pi}(\theta) \propto L(\theta)\pi(\theta)$ to be stationary.

[Cappé et al., 2000]

- Motivations

Setup

► All MCMC schemes presented here target an extended distribution on 3 = ℝ^d × ℝ^d

$$\rho(z) = \pi(x) \times \psi(v) = \exp(-H(z))$$

where z = (x, v) extended state and $\Psi(v)$ [by default] multivariate standard Normal

 Physics takes v as velocity or momentum variables allowing for a deterministic dynamics on R^d

• Obviously sampling from ρ provides samples from π

Piecewise deterministic Markov process

Piecewise deterministic Markov process $\{\mathbf{z}_t \in \mathcal{Z}\}_{t \in [0,\infty)}$, with three ingredients,

1. **Deterministic dynamics**: between events, deterministic evolution based on ODE

$$d\mathbf{z}_t/dt = \Phi(\mathbf{z}_t)$$

- 2. Event occurrence rate: $\lambda(t) = \lambda(\mathbf{z}_t)$
- Transition dynamics: At event time, τ, state prior to τ denoted by z_{τ-}, and new state generated by z_τ ~ Q(·|z_{τ-}).
 [Davis, 1984, 1993]

Piecewise Deterministic Versions

Simulation by superposition theorem

Theorem (Kingman, 1992)

Let Π_1, Π_2, \cdots , be countable collection of independent Poisson processes on \mathbb{R}^+ with resp. rates $\lambda_n(\cdot)$. If $\sum_{n=1}^{\infty} \lambda_n(t) < \infty$ for all *t*'s, then superposition process is Poisson process with rate lambda(t)

Decomposition of $U = \sum_{j} U_{j}$ plus thinning

Simulation by superposition plus thinning

Almost all implementations of discrete-time schemes of consist of sampling a Bernoulli of parameter $\alpha(z)$ For $\Phi(z) = (x + v\epsilon, v)$ and $\alpha(z) = 1 \wedge \pi(x + v\epsilon)/\pi(x)$, sampling inter-event time for strictly convex U can be obtained by solving $t^* = \arg \min U(x + vt)$ and additional randomization

- ▶ thinning: if there exists $\bar{\alpha}$ such that $\alpha(\Phi^k(z)) \geq \bar{\alpha}(x,k)$, accept-reject
- superposition and thinning: when $\alpha(z) = 1 \wedge \rho(\Phi(z)) / \rho(z)$ and $\rho(\cdot) = \prod_i \rho_i(\cdot)$ then $\bar{\alpha}(z,k) = \prod_i \bar{\alpha}_i(z,k)$

└─Versions of PDMP

Extended generator

Definition

For $\mathcal{D}(\mathcal{L})$ set of measurable functions $f: \mathcal{Z} \to \mathbb{R}$ such that there exists a measurable function $h: \mathcal{Z} \to \mathbb{R}$ with $t \to h(\mathbf{z}_t) P_{\mathbf{z}}$ -a.s. for each $\mathbf{z} \in \mathcal{Z}$ and the process

$$C_t^f = f(\mathbf{z}_t) - f(\mathbf{z}_0) - \int_0^t h(\mathbf{z}_s) ds$$

a local martingale. Then we write $h = \mathcal{L}f$ and call $(\mathcal{L}, \mathcal{D}(\mathcal{L}))$ the extended generator of the process $\{\mathbf{z}_t\}_{t \geq 0}$.

└─Versions of PDMP

Extended Generator of PDMP

Theorem (Davis, 1993)

The generator, \mathcal{L} , of above PDMP is, for $f \in \mathcal{D}(\mathcal{L})$

$$\mathcal{L}f(\mathbf{z}) = \nabla f(\mathbf{z}) \cdot \Phi(\mathbf{z}) + \lambda(\mathbf{z}) \int_{\mathbf{z}'} \left[f(\mathbf{z}') - f(\mathbf{z}) \right] Q(d\mathbf{z}'|\mathbf{z})$$

Furthermore, $\mu(d\mathbf{z})$ is an invariant distribution of above PDMP, if

$$\int \mathcal{L}f(\mathbf{z})\mu(d\mathbf{z}) = 0, \quad \text{for all } f \in \mathcal{D}(\mathcal{L})$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへで

Zig-Zag Sampler (Bierkens et al., 2016)

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

Zig-Zag Sampler (Bierkens et al., 2016)

- $\mathcal{V} = \{+1, -1\}^d$, and $\pi(\mathbf{v}|\mathbf{x}) \sim \mathsf{Uniform}(\{+1, -1\}^d)$
 - 1. Deterministic dynamics:

$$d\mathbf{x}_t/dt = \mathbf{v}_t, d\mathbf{v}_t/dt = \mathbf{0}$$

2. Event occurrence rate:

$$\lambda(\mathbf{x}, \mathbf{v}) = \sum_{i=1}^{d} \lambda_i(\mathbf{x}, \mathbf{v}) = \sum_{i=1}^{d} \left[\left\{ v_i \nabla_i U(\mathbf{x}) \right\}_+ + \lambda_i^{\mathsf{ref}} \right]$$

3. Transition dynamics:

$$Q((d\mathbf{x}', d\mathbf{v}')|(\mathbf{x}, \mathbf{v})) = \sum_{i=1}^{d} \frac{\lambda_i(\mathbf{x}, \mathbf{v})}{\lambda(\mathbf{x}, \mathbf{v})} \delta_{\mathbf{x}}(d\mathbf{x}') \delta_{F_i \mathbf{v}}(d\mathbf{v}')$$

where F_i operator that flips *i*-th component of \mathbf{v} and keep others unchanged

Continuous-time Hamiltonian Monte Carlo (Neal, 1999)

$$\mathcal{V} = \mathbb{R}^d$$
, and $\pi(\mathbf{v}|\mathbf{x}) = arphi(\mathbf{v}) \sim \mathcal{N}(0, I_d)$

1. Deterministic dynamics:

$$d\mathbf{x}_t/dt = \mathbf{v}_t, d\mathbf{v}_t/dt = -\nabla U(\mathbf{x}_t)$$

- 2. Event occurrence rate: $\lambda(\mathbf{x}, \mathbf{v}) = \lambda_0(\mathbf{x})$
- 3. Transition dynamics:

$$Q((d\mathbf{x}', d\mathbf{v}')|(\mathbf{x}, \mathbf{v})) = \delta_{\mathbf{x}}(d\mathbf{x}')\varphi(d\mathbf{v}')$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

Continuous-time Riemannian Manifold HMC (Girolami & Calderhead, 2011)

 $\mathcal{V} = \mathbb{R}^d$, and $\pi(\mathbf{v}|\mathbf{x}) = \mathcal{N}(0, G(\mathbf{x}))$, the Hamiltonian is

$$H(\mathbf{x}, \mathbf{v}) = U(\mathbf{x}) + \frac{1}{2}\mathbf{v}^T G(\mathbf{x})^{-1}\mathbf{v} + \frac{1}{2}\log(|G(\mathbf{x})|)$$

1. Deterministic dynamics:

$$d\mathbf{x}_t/dt = \partial H/\partial \mathbf{v}(\mathbf{x}_t, \mathbf{v}_t), d\mathbf{v}_t/dt = -\partial H/\partial \mathbf{x}(\mathbf{x}_t, \mathbf{v}_t)$$

- 2. Event occurrence rate: $\lambda(\mathbf{x}, \mathbf{v}) = \lambda_0(\mathbf{x})$
- 3. Transition dynamics:

$$Q((d\mathbf{x}', d\mathbf{v}')|(\mathbf{x}, \mathbf{v})) = \delta_{\mathbf{x}}(d\mathbf{x}')\varphi(d\mathbf{v}'|\mathbf{x}')$$

Randomized BPS

Define

$$\mathbf{a} = \frac{\langle \mathbf{v}, \nabla U(\mathbf{x}) \rangle}{\langle \nabla U(\mathbf{x}), \nabla U(\mathbf{x}) \rangle} \nabla U(\mathbf{x}), \quad \mathbf{b} = \mathbf{v} - \mathbf{a}$$

Regular BPS, move $\mathbf{v}' = -\mathbf{a} + \mathbf{b}$ Alternatives

1. (Fearnhead et al., 2016):

$$\mathbf{v}' \sim Q_{\mathbf{x}}(d\mathbf{v}'|\mathbf{v}) = \max\{0, \langle -\mathbf{v}', \nabla U(\mathbf{x}) \rangle\} d\mathbf{v}'$$

2. (Wu & X, 2017): $\mathbf{v}' = -\mathbf{a} + \mathbf{b}'$, where \mathbf{b}' Gaussian variate over the space orthogonal to $\nabla U(\mathbf{x})$ in \mathbb{R}^d .

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

HMC-BPS (Vanetti et al., 2017) $\rho(\mathbf{x}) \propto \exp\{-V(\mathbf{x})\}$ is a Gaussian approximation of the target $\pi(\mathbf{x})$.

$$\hat{H}(\mathbf{x}, \mathbf{v}) = V(\mathbf{x}) + 1/2\mathbf{v}^T \mathbf{v}, \quad \tilde{U}(\mathbf{x}) = U(\mathbf{x}) - V(\mathbf{x})$$

1. Deterministic dynamics:

$$d\mathbf{x}_t/dt = \mathbf{v}_t, d\mathbf{v}_t/dt = -\nabla V(\mathbf{x}_t)$$

- 2. Event occurrence rate: $\lambda(\mathbf{x}, \mathbf{v}) = \langle \mathbf{v}, \nabla \tilde{U}(\mathbf{x}) \rangle_+ + \lambda^{\text{ref}}$
- 3. Transition dynamics:

$$\begin{split} Q((d\mathbf{x}', d\mathbf{v}')|(\mathbf{x}, \mathbf{v})) \\ &= \frac{\langle \mathbf{v}, \nabla \tilde{U}(\mathbf{x}) \rangle_{+}}{\lambda(\mathbf{x}, \mathbf{v})} \delta_{\mathbf{x}}(d\mathbf{x}') \delta_{R_{\nabla \tilde{U}(\mathbf{x})}\mathbf{v}}(d\mathbf{v}') + \frac{\lambda^{\mathsf{ref}}}{\lambda(\mathbf{x}, \mathbf{v})} \delta_{\mathbf{x}}(d\mathbf{x}') \varphi(d\mathbf{v}') \end{split}$$

└─Versions of PDMP

Discretisation

 Sherlock & Thiery (2017) considers delayed rejection approach with only point-wise evaluations of target, by making speed flip move once proposal involving flip in speed and drift in variable of interest rejected. Also add random perturbation for eergodicity, plus another perturbation based on a Brownian argument. Requires calibration

2. Vanetti et al. (2017)

Benefit: bypassing the generation of inter-event time of inhomogeneous Poisson processes.

└─Versions of PDMP

Discretisation

1. Sherlock & Thiery (2017)

2. Vanetti et al. (2017) unifies many threads and relates PDMP, HMC, and discrete versions, with convergence results. Main idea improves upon existing deterministic methods by accounting for target. Borrows from earlier slice sampler idea of Murray et al. (AISTATS, 2010), exploiting exact Hamiltonian dynamics for approximation to true target. Except that bouncing avoids the slice step. Eight discrete BPS both correct against target and do not simulating event times.

Benefit: bypassing the generation of inter-event time of inhomogeneous Poisson processes.

The End
