Rare events in complex dynamical systems: the examples of the climate and the solar system dynamics

F. BOUCHET – ENS de Lyon and CNRS
With J. WOUTERS and F. RAGONE (heat waves), and E. WOILLEZ (astronomy)

Large deviation theory and climate.
Outline

1. Rare events in complex dynamical systems and instanton phenomenology
   - Rare events with a huge impact: examples in turbulent flows
   - Rare and extreme events in astronomy
   - Rare events with a huge impact: extreme heat waves

2. Instanton for the destabilization of the solar system by Mercury
   - Is the solar system stable?
   - The dynamical mechanism for Mercury destabilization
   - First exit time and instanton for Mercury–Jupiter resonance

3. Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm
Outline

1. Rare events in complex dynamical systems and instanton phenomenology
   - Rare events with a huge impact: examples in turbulent flows
   - Rare and extreme events in astronomy
   - Rare events with a huge impact: extreme heat waves

2. Instanton for the destabilization of the solar system by Mercury
   - Is the solar system stable?
   - The dynamical mechanism for Mercury destabilization
   - First exit time and instanton for Mercury–Jupiter resonance

3. Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm
Lattice Boltzmann Simulations of 2D Flows

Velocity ($Re_G = 1200$, $Re_O \approx 500$)
Extreme Drags for 2D Grid Turbulence Flows

Velocity ($Re_G = 1200$, $Re_O \simeq 500$) (with T. Lestang)
Predictability of Extreme Patterns for Turbulent Flows

Streamlines and pressure for the four most extreme drag events

- Extreme event patterns are often predictable. Instanton?
Freidlin–Wentzell Theory

\[ \frac{dx}{dt} = b(x) + \sqrt{2\varepsilon}\eta(t) \]

- Path integral representation of transition probabilities:

\[ P(x_T, T; x_0, 0) = \int_{x(0) = x_0}^{x(T) = x_T} e^{-\frac{\mathcal{A}_T[x]}{\varepsilon}} \mathcal{D}[x] \]

with \( \mathcal{A}_T[x] = \int_0^T \mathcal{L}[x, \dot{x}] \, dt \) and \( \mathcal{L}[x, \dot{x}] = \frac{1}{4} [\dot{x} - b(x)]^2 \).

- We may consider the \( \varepsilon \to 0 \) limit, using a saddle point approximation (WKB), then we obtain the large deviation result

\[ P(x_T, T; x_0, 0) \asymp e^{-\min_{\{x(t)\}} \left\{ \mathcal{A}_T[x] | x(0) = x_0 \text{ and } x(T) = x_T \right\} / \varepsilon} \]
Most Transition Paths Follow the Instanton

- In the weak noise limit, most transition paths follow the most probable path (instanton)

\[ P(x_1, T; x_{-1}, 0) \approx e^{-\frac{\Delta V}{k_B T_e}}. \]

- For gradient dynamics, instantons are time reversed relaxation paths from a saddle to an attractor. Arrhenius law then follows.
Rare Transitions Between Quasigeostrophic Jets

Rare transitions for quasigeostrophic jets (with E. Simonnet)

- How to predict those rare transitions transition rates? What is their probability? Which theoretical approach?

F. Bouchet CNRS–ENSL

Large deviation theory and climate.
Atmosphere Jet “Instantons” Computed using the AMS
AMS: an algorithm to compute rare events, for instance rare reactive trajectories

Transition trajectories between 2 and 3 jet states

- The dynamics of turbulent transitions is predictable.
- Asymmetry between forward and backward transitions.
Outline

1. Rare events in complex dynamical systems and instanton phenomenology
   - Rare events with a huge impact: examples in turbulent flows
   - Rare and extreme events in astronomy
   - Rare events with a huge impact: extreme heat waves

2. Instanton for the destabilization of the solar system by Mercury
   - Is the solar system stable?
   - The dynamical mechanism for Mercury destabilization
   - First exit time and instanton for Mercury–Jupiter resonance

3. Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm

F. Bouchet CNRS–ENSL

Large deviation theory and climate.
Collisional Trajectories in the Solar System
In collaboration with J. Laskar.

Distance from the sun vs time (J. Laskar)
\((7 \cdot 10^6 \text{ hours of CPU, } p=1/100\,000)\)

- What are the probabilities of past and future qualitative changes of the solar system?

Collision probability?
Outline

1. Rare events in complex dynamical systems and instanton phenomenology
   - Rare events with a huge impact: examples in turbulent flows
   - Rare and extreme events in astronomy
   - Rare events with a huge impact: extreme heat waves

2. Instanton for the destabilization of the solar system by Mercury
   - Is the solar system stable?
   - The dynamical mechanism for Mercury destabilization
   - First exit time and instanton for Mercury–Jupiter resonance

3. Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm
Extreme Heat Waves
Example: the 2003 heat wave over western Europe

The Return Time of Extreme Heat Waves

At a fixed numerical cost, with the large deviation algorithm, we can study events which are several orders of magnitude rarer than the ones we could study with the control run.

F. Bouchet CNRS–ENSL
Large deviation theory and climate.

Outline

1 Rare events in complex dynamical systems and instanton phenomenology
   - Rare events with a huge impact: examples in turbulent flows
   - Rare and extreme events in astronomy
   - Rare events with a huge impact: extreme heat waves

2 Instanton for the destabilization of the solar system by Mercury
   - Is the solar system stable?
   - The dynamical mechanism for Mercury destabilization
   - First exit time and instanton for Mercury–Jupiter resonance

3 Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm
$g_1 - g_5$ (Mercury–Jupiter) resonance plays a crucial role for Mercury destabilization (Laskar, Gastineau, Batygin and Laughlin (2008 and 2009)).
Fast increase of Mercury eccentricity because of a resonance with Jupiter. (time scale 1My) (Boué, Laskar and Farago, 2012)

- Mercury--Jupiter resonance explains Mercury destabilization for $e > 0.7$.
- How does this all start?
The Batygin–Morbidelli–Holman Model for Mercury
$s_1 - s_2$ and $g_1 - g_2$ resonances play a major role.

\[ H := H_0(I, J) + E_{g_5} \sqrt{I} \cos(\varphi + g_5 t + \beta_5) + E_{s_2} \sqrt{J} \cos(\psi + s_2 t + \theta_2) + E_{g_2} \sqrt{I} \cos(\varphi + g_2 t + \beta_2) \]

\[ I \approx \frac{e^2}{2}, \quad J \approx \frac{i^2}{2}, \quad \varphi = -\varpi, \quad \psi = -\Omega. \]

- A time dependent Hamiltonian system with 2 degrees of freedom (Batygin, Morbidelli and Holman, 2015).
Resonance Maps in the Action Space

Resonance map for the BMH model

F. Bouchet CNRS–ENSL
Large deviation theory and climate.
Resonant and Non-Resonant Perturbations

- **Canonical transform:** \( \tilde{\phi} = \phi + g_5 t + \beta_5, \quad \tilde{\psi} = \psi + s_2 t + \theta_2, \)

\[
H := \tilde{H} + H_{pert}
\]

\[
\tilde{H} := H_0(I, J) + g_5 I + s_2 J + E g_5 \sqrt{I} \cos(\tilde{\phi}) + E s_2 \sqrt{J} \cos(\tilde{\psi})
\]

- Key idea: higher order resonances are small perturbations. They have a small long term effect than can be dealt with using stochastic averaging.
Slow Diffusion of the Effective Hamiltonian

Hamiltonian (green) and effective Hamiltonian (blue) dynamics
Stochastic Averaging for the Slow Hamiltonian

\[ \tilde{H} := H_0(l, J) + g_5 l + s_2 J + E g_5 \sqrt{l} \cos(\tilde{\phi}) + E s_2 \sqrt{J} \cos(\tilde{\psi}) \]

is a good slow variable.

**Stochastic averaging:** we get diffusion equation

\[ \frac{d \langle \tilde{H} \rangle}{dt} = D \xi(t) \]

Using Lie transform, we can estimate the order of magnitude of \( D \):

\[ \frac{D_{th}}{D_{empirical}} = 0.65 \]
Diffusion on the Level Lines of the Slow Hamiltonian

The effective Hamiltonian level lines in the action space

- We have mapped the dynamics on a first exit time problem for an effective diffusion.
Outline

1. Rare events in complex dynamical systems and instanton phenomenology
   - Rare events with a huge impact: examples in turbulent flows
   - Rare and extreme events in astronomy
   - Rare events with a huge impact: extreme heat waves

2. Instanton for the destabilization of the solar system by Mercury
   - Is the solar system stable?
   - The dynamical mechanism for Mercury destabilization
   - First exit time and instanton for Mercury–Jupiter resonance

3. Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm

F. Bouchet  CNRS–ENSL  Large deviation theory and climate.
The First Exit Time for a Diffusion

Boundary conditions for the effective diffusion
First exit time probability for the Mercury–Jupiter resonance -
$\tau^* \approx 12.4$ Gyr

- There is a pretty good agreement between the the HMG model and the diffusive model for the effective Hamiltonian.
Should the Exit Dynamics be Predictable (Instantons)?

First exit time probability for the Mercury–Jupiter resonance

- We expect short time instantons for the dynamics towards Jupiter–Mercury resonance.
Short Time Instanton for the Brownian Motion

Samples of trajectories with exit time $\tau$

- For a free diffusion, the instanton is a straight line.
Instanton for Mercury–Jupiter Resonance
For the Batygin–Morbidelli–Holman model

There is an excellent agreement between the BMH model and the effective Hamiltonian diffusion.
Summary and Perspectives

- The dynamical processes leading to Mercury–Jupiter resonance can be understood qualitatively.
- Within the Batygin–Morbidelli–Holman model, Mercury–Jupiter resonance typically occurs within 12 G.yr. and is rare for much shorter time scales.
- The several hundred thousand year destabilization of the inner solar system is rare and follows an instanton dynamics.
- We aim at quantifying this instanton behavior for realistic models, using rare event algorithms (with J. Laskar).

Extreme Heat Waves and Anticyclonic Anomalies

2010 Heat Wave over Eastern Europe (Dole and col., 2011)
The Jet Stream, Rossby Waves, and Blocking Events

Higher troposphere winds (NASA)
Anthropogenic Causes of the 2010 Heat Wave

(Dole et al., 2011)

- A clear anthropogenic impact.
- What are the dynamical mechanisms for such extreme events?

(otto et al., 2012)
The scientific questions:
- What is the probability and the dynamics of those rare events?
- How to sample rare events?
- Are direct numerical simulations a reasonable approach?
We use the Planet Simulator (PlaSim) model (an Earth system model of intermediate complexity) developed at Hamburg.

- T42 horizontal resolution (64x128 grid points), 10 vertical layers, about $10^5 - 10^6$ degrees of freedom.
Plasim Northern Hemisphere Dynamics

500 HPa geopotential height and temperature anomalies
The observable will be Europe averaged surface temperature

\[ a = \frac{1}{T} \int_0^T dt \langle Temp \rangle_{Europe}(t) \]
45-Day Averaged Temperature over Europe (Plasim Model)

Full timeseries

\[ a = \frac{1}{T} \int_0^T dt \langle \text{Temp} \rangle_{\text{Europe}}(t) \text{ with } T=45 \text{ days} \]
Outline

1. Rare events in complex dynamical systems and instanton phenomenology

3. Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm
Large Variances for Estimators of Rare Event Probabilities

- Monte Carlo sampling of small probabilities (sampling the probability from iid random variables)

\[ \gamma_A = \int dx \rho(x)1_A(x) = \mathbb{E}(1_A). \]  
Estimator: \( \hat{\gamma}_A = \frac{1}{N} \sum_{n=1}^{N} 1_A(X_n). \)

- The variance of \( \hat{\gamma}_A \) is \( \text{Var}(1_A)/N = (\gamma_A - \gamma_A^2)/N. \) The relative error is

\[ \text{Er} \sim \frac{1}{\sqrt{\gamma_A N}}. \]

- The number of observations has to grow at least as fast as the probability decreases to keep the relative error constant.
We sample a tilted probability with PDF $\tilde{\rho}(x)$.

$$\gamma_A = \int_A \rho(x) \, dx = \int_A L(x) \tilde{\rho}(x) \, dx.$$  Estimator $\hat{\gamma}_A = \frac{1}{N} \sum_{n=1}^N L(X_n) 1_A(X_n)$.

If $L$ is well chosen, rare events for $\rho$ are common for $\tilde{\rho}$, and the variance is much lower.

How to perform importance sampling for a climate model?
Donsker–Varadhan Large deviations for time averaged observables

- Donsker–Varadhan: large time asymptotics for time averaged observables.

- Time averaged observables

\[ P \left[ \frac{1}{T} \int_0^T \langle \text{Temp} \rangle_{\text{Europe}} \, dt = a \right] \sim_{T \to \infty} C e^{-TL[a]} . \]

- \( I(a) \) is the large deviation rate function. It has a minimum for the most probable value \( a_* \), its second derivative at \( a_* \) describes the Gaussian fluctuations, but it describes also much rarer fluctuations.
Numerical Computation of Donsker–Varadhan Large Deviations

- Importance sampling: how to sample efficiently the tilted distribution

\[ \tilde{P}_k(\{X(t)\}_{0 \leq t \leq T}) = \frac{1}{\exp(T \lambda(k))} P_0(\{X(t)\}_{0 \leq t \leq T}) \exp \left[ k \int_0^T A(X(t)) \, dt \right] \]

- We use the Giardina–Kurchan–Leconte–Tailleur algorithm (Giardina et al 2006).
- We consider an ensemble of \( N \) trajectories \( \{x_n(t)\} \). At each time \( t_i = i \tau \), each trajectory may be killed or cloned according to the weights

\[ \frac{1}{W_i(k)} \exp \left( k \int_{t_{i-1}}^{t_i} A(x_n(t)) \, dt \right) \quad \text{with} \quad W_i(k) = \sum_{n=1}^{N} \exp \left( k \int_{t_{i-1}}^{t_i} A(x_n(t)) \, dt \right). \]
Genealogical Algorithm: Selecting and Cloning Trajectories
The trajectory statistics is tilted towards the events of interest.

Sample paths for the GKLT algorithm
(from Bouchet, Jack, Lecomte, Nemoto, 2016)

- Computing numerically Donsker–Varadhan large deviations through a genealogical algorithm.
1. Rare events in complex dynamical systems and instanton phenomenology
   - Rare events with a huge impact: examples in turbulent flows
   - Rare and extreme events in astronomy
   - Rare events with a huge impact: extreme heat waves

2. Instanton for the destabilization of the solar system by Mercury
   - Is the solar system stable?
   - The dynamical mechanism for Mercury destabilization
   - First exit time and instanton for Mercury–Jupiter resonance

3. Probability and dynamics of extreme heat waves
   - The jet stream, blocking events, and heat waves
   - Large deviations for time averaged observables
   - Sampling extreme heat waves using a large deviation algorithm
PDF of time averaged temperature

- At a fixed numerical cost, we get hundreds more heat waves with the large deviation algorithm than with the control run.
- We can consider interesting dynamical studies.

Heat wave number
The Return Times of Extreme Heat Waves

Return time of 90 day European heat waves

- At a fixed numerical cost, with the large deviation algorithm, we can study events which are several orders of magnitude rarer than the ones we could study with the control run.

F. Ragone, J. Wouters, and F. Bouchet, PNAS, 2017

F. Bouchet CNRS–ENSL

Large deviation theory and climate.
A Typical Heat Wave

500 HPa geopotential height and temperature anomalies
Heat Wave Conditional Statistics and Teleconnection Patterns

500 HPa geopotential height anomalies and temperature anomalies

Heat wave statistics defined as statistics conditioned with
\[
\frac{1}{T} \int_0^T \langle Temp \rangle_{\text{Europe}}(t) \, dt > 2^\circ C, \text{ with } T = 40 \text{ days}.
\]
July 2018 Heat Waves

Observed (reanalysis) July 2018 500 HPa geopotential height and temperature anomalies with respect to the last ten years.
Heat Waves and Shift of the Jet Stream

Northern hemisphere mean kinetic energy

The European heat waves are associated with a northward shift of the jet stream over Europe and a southward shift over Asia.

Kinetic energy anomaly during the heat waves
Conclusions:

- Large deviation algorithms provide a wonderful tool to sample rare events, for instance heat waves.
- It should open a new range of dynamical studies in GCM, even the more complex ones.

Work in progress:

- A dynamical study of heat waves based on hundreds of sampled heat waves.
- Relation with blocking events? Are they different types of dynamics leading to heat waves? Which physical processes? Relation between heat waves precursors and instantons?

F. Ragone, J. Wouters, and F. Bouchet, PNAS, 2018
