Multiscale Substitution Tilings

Yaar Solomon

Department of Mathematics Ben-Gurion University of the Negev.

Based on a joint work with Yotam Smilansky (Rutgers) 6-10 December, 2021

A short introduction to my field

In aperiodic order we study properties infinite patterns, and of spaces of patterns, usually for their dynamical properties.

Penrose tiling - from Wikipedia

A multiscale tiling

The patterns are often non-periodic, but their "order" is manifested in other lattice-like properties, such as:

Finite local complexity (FLC):

the set of patches of a fixed size is finite.

Repetitivity:

Self similarity

- By repeated subdivisions, and rescaling, one tile larger and larger regions, with the same set of tiles.
- As a limit of these, one gets a tiling of the whole space.

- By repeated subdivisions, and rescaling, one tile larger and larger regions, with the same set of tiles.
- As a limit of these, one gets a tiling of the whole space.

- By repeated subdivisions, and rescaling, one tile larger and larger regions, with the same set of tiles.
- As a limit of these, one gets a tiling of the whole space.

Example : Penrose tiling
Substitution rule :

- By repeated subdivisions, and rescaling, one tile larger and larger regions, with the same set of tiles.
- As a limit of these, one gets a tiling of the whole space.

Example : Penrose tiling
Substitution rule :

 By repeated subdivisions, and rescaling, one tile larger and larger regions, with the same set of tiles.

 As a limit of these, one gets a tiling of the whole space.

Substitution rule :

 By repeated subdivisions, and rescaling, one tile larger and larger regions, with the same set of tiles.

 As a limit of these, one gets a tiling of the whole space.

Definitions - Multiscale substitution scheme

A multiscale substitution scheme $\sigma = (\tau_{\sigma}, \varrho_{\sigma})$ in \mathbb{R}^d consists of a list of prototiles $\tau_{\sigma} = (T_1, \ldots, T_n)$, and a substitution rule defining a partition $\varrho_{\sigma}(T_i)$ of each prototile T_i , so that every tile in $\varrho_{\sigma}(T_i)$ is a translation of a rescaled copy of a prototile in τ_{σ} , where multiple scales are allowed!.

Example 1: $\tau_{\sigma} = \{S\}$:

Definitions - Multiscale substitution scheme

A multiscale substitution scheme $\sigma = (\tau_{\sigma}, \varrho_{\sigma})$ in \mathbb{R}^d consists of a list of prototiles $\tau_{\sigma} = (T_1, \ldots, T_n)$, and a substitution rule defining a partition $\varrho_{\sigma}(T_i)$ of each prototile T_i , so that every tile in $\varrho_{\sigma}(T_i)$ is a translation of a rescaled copy of a prototile in τ_{σ} , where multiple scales are allowed!.

Example 1: $\tau_{\sigma} = \{S\}$:

Definitions - Multiscale substitution scheme

Example 2: $\tau_{\sigma} = \{S, R\}$: We assume that prototiles are of volume 1.

Those numbers are referred to as the *scales*.

Repeated subdivisions fails for multiple scales

Repeated subdivisions fails for multiple scales

Repeated subdivisions fails for multiple scales

The *substitution flow* $F_t(T_i)$ is defined on the prototiles as follows:

• At time t = 0, $F_0(T_i) = T_i$.

For t > 0, F_t(T_i) is the patch obtained by inflating T_i by e^t and then repeatedly subdivide tiles, via the substitution rule, until all tiles are of volume ≤ 1.

Yaar Solomon Multiscale Substitution Tilings

æ

- *Multiscale substitution tilings* are tilings of \mathbb{R}^d that are limits of (translations of) those patches, $F_t(T_i)$.
- Limits are taken with respect to a natural compact topology in which two tilings / patches are close if when looking at a large centered ball they are close in the Hausdorff metric.
- The *tiling space* X_σ is the space of all these limit objects. With the action of R^d by translation, (X_σ, R^d) becomes a nice, compact, dynamical system.

Graph model for multiscale substitution schemes

Let $\sigma = (\tau_{\sigma}, \varrho_{\sigma})$ be a multiscale substitution scheme.

• σ is called *irreducible* if the associated graph G_{σ} is strongly connected.

σ is called *incommensurable* if the associated graph G_σ contains two closed paths of lengths a, b, where a ∉ Qb.

• Our project focuses on schemes that are irreducible and incommensurable.

The graph models the flow - Kakutani

Important Observation

{tiles in $F_t(T_i)$ } \longleftrightarrow {paths of lengths t from T_i in G_σ }

Theorem (Kiro-Smilansky \times 2 '20, Smilansky \geq ' 21)

Let σ be an irreducible incommensurable scheme in \mathbb{R}^d . Then

$$\#\{\text{tiles in } F_t(T_i)\} = C_\sigma e^{dt} + ERROR,$$

where C_{σ} is explicit and ERROR = $o(e^{dt})$, $t \rightarrow \infty$.

The constant C_{σ} is given explicitly in a recent paper of Smilansky in term of the following three matrices:

$$(S)_{ij} = \# \left\{ \begin{array}{l} \text{tiles of type} \\ j \text{ in } \varrho_{\sigma}(T_i) \end{array} \right\}, \quad (V)_{ij} = \sum_{\substack{\text{tiles of type} \\ j \text{ in } \varrho_{\sigma}(T_i)}} \operatorname{vol}(T),$$
$$(H)_{ij} = \sum_{\substack{\text{tiles of type} \\ j \text{ in } \varrho_{\sigma}(T_i)}} -\operatorname{vol}(T) \log(\operatorname{vol}(T))$$

Theorem (Smilansky, S. '21)

For every irreducible incommensurable scheme σ , $\exists k > 0$ s.t.

$$\underbrace{\left| \#\{\text{tiles in } F_t(T_i)\} - C_{\sigma} e^{dt} \right|}_{\text{ERROR}} \ge \Omega\left(\frac{e^{dt}}{t^k}\right).$$

Corollary (Smilansky, S. '21)

Every irreducible, incommensurable multiscale substitution tiling T is **not uniformly spread**.

That is, if Λ is a point set obtained from the tiling \mathcal{T} by placing a point in each tile, every bijection $\varphi : \Lambda \to \mathbb{Z}^d$ will have points that are mapped "arbitrarily far away" from where they are.

Theorem (Smilansky, S. '21)

For every irreducible incommensurable scheme σ , $\exists k > 0$ s.t.

$$\underbrace{\#\{\text{tiles in } F_t(T_i)\} - C_{\sigma} e^{dt}}_{\text{ERROR}} \ge \Omega\left(\frac{e^{dt}}{t^k}\right).$$

Corollary (Smilansky, S. '21)

Every irreducible, incommensurable multiscale substitution tiling T is **not uniformly spread**.

That is, if Λ is a point set obtained from the tiling \mathcal{T} by placing a point in each tile, every bijection $\varphi : \Lambda \to \mathbb{Z}^d$ will have points that are mapped "arbitrarily far away" from where they are.

 The irreducibility and incommensurability of G_σ can also be applied to study the dynamical system (X_σ, R^d).

Theorem (Smilansky, S. '21)

The dynamical system $(\mathbb{X}_{\sigma}, \mathbb{R}^d)$ is minimal.

• Geometric interpretation:

Corollary (Smilansky, S. '21)

- Every multiscale tiling is (almost) repetitive.
- Every two multiscale tilings in X_σ are (almost) locally indistinguishable.

 The irreducibility and incommensurability of G_σ can also be applied to study the dynamical system (X_σ, R^d).

Theorem (Smilansky, S. '21)

The dynamical system $(X_{\sigma}, \mathbb{R}^d)$ is minimal.

Geometric interpretation:

Corollary (Smilansky, S. '21)

- Every multiscale tiling is (almost) repetitive.
- 2 Every two multiscale tilings in X_σ are (almost) locally indistinguishable.
