Abstract

In this talk, we consider the Navier–Stokes–Fourier system, describing the motion of a compressible, viscous, and heat conducting fluid in a bounded domain $\Omega \subset \mathbb{R}^d$, $d = 2, 3$, with general non-homogeneous Dirichlet boundary conditions for the absolute temperature. We introduce a new concept of weak solution based on the satisfaction of the entropy inequality together with a balance law for the ballistic energy. We show the weak–strong uniqueness principle as well as the existence of global-in-time solutions.
