**Abstract.** A series of monomial representations of  $SL_2(p)$  is used to construct a new series of self-dual ternary codes of length  $2(p+1)$  for all primes  $p \geq 5$  (mod 8). In particular we find a new extremal self-dual ternary code of length 60.

## 1 Introduction

In 1969 Vera Pless [6] discovered a family of self-dual ternary codes  $P(p)$  of length  $2(p+1)$  for primes  $p$  with  $p \equiv -1 \pmod{6}$ . Together with the extended quadratic residue codes  $XQR(q)$  of length  $q+1$  ( $q$  prime,  $q \equiv \pm 1 \pmod{12}$ ) they define a series of self-dual ternary codes of high minimum distance (see [3, Chapter 16, §8]). For  $p=5$ , the Pless code  $P(5)$  coincides with the Golay code  $\mathcal{G}_{12}$  which is also the extended quadratic residue code  $XQR(11)$  of length 12.

Using invariant theory of finite groups, A. Gleason [2] has shown that the minimum distance of a self-dual ternary code of length  $4n$  cannot exceed  $3\lfloor \frac{n}{2} \rfloor + 3$ . Self-dual codes that achieve equality are called *extremal*. Both constructions, the Pless symmetry codes and the extended quadratic residue codes yield extremal ternary self-dual codes for small values of  $p$ .

It is known<sup>2</sup> that the Pless symmetry code  $C(q)$  of length  $n = 2q + 2$ , where  $q \equiv -1 \pmod{3}$  is an odd prime power, contains a set of  $n$  codewords of weight  $n$ , which after replacing every entry equal to 2 by  $-1$  form the rows of a Hadamard matrix equivalent to the Paley-Hadamard matrix of type II.

In particular, the Pless symmetry code  $C(17)$  contains the rows of a Hadamard matrix  $P$  of Paley type II, having a full automorphism group of order  $4 \cdot 17(17^2 - 1) = 19584$ , and the rows of  $P$  span the code  $C(17)$ .

<sup>2</sup>V. Pless, Symmetry codes over  $GF(3)$  and new five-designs, *J. Combin. Theory, Ser. A* **12** (1972), 119-142.

Recently, Tonchev showed<sup>3</sup> that the code  $C(17)$  contains a second equivalence class of Hadamard matrices of order 36 having as rows codewords of  $C(17)$ .

- Any matrix  $H$  from the second equivalence class has a full automorphism group of order 72 and the rows of  $H$  span the code  $C(17)$ .
- In addition,  $H$  is monomially equivalent to a regular Hadamard matrix  $H'$ , such that every row of  $H'$  has 15 entries equal to  $-1$  and 21 entries equal to 1, thus  $H'$  has a constant row sum 6. The symmetric 2-(36, 15, 6) design  $D$  with a  $(0, 1)$ -incidence obtained by replacing every entry 1 of  $H'$  with 0 and every entry  $-1$  of  $H'$  with 1 has a trivial full automorphism group, and the row span of its incidence matrix over  $GF(3)$  is equivalent to the Pless symmetry code  $C(17)$ .

⇒ Hadamard matrices derived from the symmetry code of length 36?

On extremal ternary self-dual codes of length 36 and related symmetric 2-(36, 15, 6) designs

Motivation - known facts

Hadamard matrices derived from the symmetry code of length 36

Symmetric 2-(36, 15, 6) designs with an involution and their ternary codes

- The code  $C(17)$  contains exactly 888 codewords of weight 36. In what follows, we denote by  $U$  the set of all 888 codewords in  $C(17)$  of full weight. The 3-rank (that is, the rank over the finite field of order 3,  $GF(3)$ ) of the matrix having as rows the codewords from  $U$  is 18, hence  $U$  spans  $C(17)$ . In the context of Hadamard matrices, we view the codewords from  $U$  as vectors with components  $\pm 1$ .
- We consider Hadamard matrices of order 36 whose rows are obtained from codewords of full weight 36 in the ternary Pless symmetry code  $C(17)$  after replacing all codeword entries that are equal to 2 with  $-1$ .

## Lemma

*A set  $S$  of 36 codewords from  $U$  is the row set of a Hadamard matrix of order 36 if and only if the Hamming distance between every two codewords from  $S$  is 18.*

## Lemma

*If  $H$  is a Hadamard matrix whose rows are codewords from  $U$  then the row set of any normalized Hadamard matrix obtained from  $H$  belongs to a code which is monomially equivalent to  $C(17)$ .*

The set  $U$  of the Pless symmetry code  $C(17)^{78}$ , does not contain the all-one codeword  $\bar{1} = (1, \dots, 1)$ , while it contains a codeword  $v$  with one entry equal to  $-1$ , located in the code coordinate labeled by  $\infty$ , and 35 entries equal to 1.

Negating (that is, multiplying by 2 (mod 3)) the code coordinate of  $C(17)$  labeled by  $\infty$  transforms the symmetry code  $C(17)$  into a monomially equivalent code  $L(17)$  which does contain the all-one vector  $\bar{1}$ <sup>9</sup>.

$\#x$	$(w_1(x), w_2(x))$
1	(0,36)
408	(15,21)
70	(18,18)
408	(21,15)
1	(36,0)

If  $x \in L(17)$  is a codeword of full weight 36, we denote by  $w_i(x)$  the number of entries of  $x$  that are equal to  $i$  ( $i = 1, 2$ ).

---

<sup>9</sup>V. D. Tonchev, On Pless symmetry codes, ternary QR codes, and related Hadamard matrices and designs, *Des. Codes Cryptogr.* 90 (2022) 2753-2762 doi.org/10.1007/s10623-021-00941-0.

All inequivalent Hadamard matrices of order 36 whose rows are obtained from codewords in  $L(17)$  of weight 36 can be enumerated as follows.

- We consider  $W$  as an  $888 \times 36$  matrix, and for every integer  $i$ ,  $1 \leq i \leq 888$ , we define a matrix  $W_i$ , being the matrix obtained by negating all columns of  $W$  which have entry  $-1$  in row  $i$ . Thus, the  $i$ th row of  $W_i$  is the all-one vector  $\bar{1}$ , and this row must be a row of every normalized Hadamard matrix consisting of rows of  $W_i$ . We refer to  $W_i$  as a matrix obtained by switching of  $W$  with respect to row  $i$ .
- To reduce the search further, we consider only normalized Hadamard matrices with first column being the all-one column.

- We define a graph  $\Gamma_i$  having as vertices all rows of  $W_i$  with first entry 1 and exactly 18 entries equal to 1, where two vertices are adjacent in  $\Gamma_i$  if and only if the Hamming distance between the corresponding rows of  $W_i$  is 18.

## Lemma

- (a) Any set of 35 rows of  $W_i$  that corresponds to a clique of size 35 in  $\Gamma_i$ , together with the all-one row  $\bar{1}$ , is the set of rows of a normalized Hadamard matrix.
- (b) The maximum clique size in  $\Gamma_i$  is 35.

One can compute representatives of the equivalence classes of Hadamard matrices by an examination of the 35-cliques in the graphs  $\Gamma_i$ ,  $1 \leq i \leq 888$ . Since every codeword  $x \in W$  with weight structure  $(w_1(x), w_2(x)) = (21, 15)$  is the negative of the codeword  $2x \in W$  with weight structure  $(15, 21)$ , it is sufficient to examine the graphs  $\Gamma_i$  such that the weight structure of the  $i$ th row of  $W$  is  $(15, 21)$  or  $(18, 18)$ .

The incidence structure with  $(0, 1)$ -incidence matrix obtained from  $W$  by replacing all entries that are equal to 2 with zero, has full automorphism group  $G$  of order 272. The group  $G$  partitions the set of 408 rows of  $W$  with weight structure  $(15, 21)$  into four orbits of lengths 68, 68, 136, 136, and the set of 70 rows with weight structure  $(18, 18)$  into four orbits of lengths 2, 17, 17, 34. Therefore, it is sufficient to examine eight switchings of  $W$ , one for each orbit, all together.

$\#x$	$(w_1(x), w_2(x))$
1	(0,36)
93	(12,24)
36	(15,21)
628	(18,18)
36	(21,15)
93	(24,12)
1	(36,0)

An examination of the matrices  $W_i$  obtained by switching of  $W$  with respect to any of the 408 rows having weight structure  $(15, 21)$  shows that any such matrix has a complete weight distribution given in the table for  $W_{408}$ , where  $W_{408}$  is obtained by the switching of  $W$  with respect to row no. 408.

On extremal ternary self-dual codes of length 36 and related symmetric 2-(36, 15, 6) designs

Motivation - known facts

Hadamard matrices derived from the symmetry code of length 36

Symmetric 2-(36, 15, 6) designs with an involution and their ternary codes

## Theorem

#x	$(w_1(x), w_2(x))$
1	(0,36)
93	(12,24)
36	(15,21)
628	(18,18)
36	(21,15)
93	(24,12)
1	(36,0)

- (a) The 36 codewords of  $W_{408}$  with weight structure (15, 21) form a regular Hadamard matrix  $H$  which is monomially equivalent to the Paley-Hadamard matrix of type II.
- (b) The symmetric 2-(36, 15, 6) design  $D$  associated with  $H$  has a full automorphism group of order 24.
- (c) The incidence matrix of  $D$  has 3-rank 18, and its linear span over  $GF(3)$  is a code equivalent to the Pless symmetry code  $C(17)$ .

Every row of the regular Hadamard matrix  $H$  from Theorem contains 15 entries equal to 1 and 21 entries equal to  $-1$ . A  $(0, 1)$ -incidence matrix  $A$  of the associated symmetric 2-(36, 15, 6) design  $D$  is obtained by adding the all-one codeword  $\bar{1}$  to every row of  $H$ , followed by a multiplication of all rows by 2 (mod 3). Hence, the ternary code spanned by the rows of  $H$  contains also the rows of  $A$ .

# Symmetric 2-(36, 15, 6) designs with an involution and their ternary codes

On extremal ternary self-dual codes of length 36 and related symmetric 2-(36, 15, 6) designs

Motivation - known facts

Hadamard matrices derived from the symmetry code of length 36

Symmetric 2-(36, 15, 6) designs with an involution and their ternary codes

- Huffman proved<sup>10</sup> that any extremal ternary self-dual code of length 36 that admits an automorphism of prime order  $p > 3$  is monomially equivalent to the Pless symmetry code.
- More recently, Eisenbarth and Nebe extended Huffman's result<sup>11</sup> by proving that the Pless symmetry code is the unique (up to monomial equivalence) ternary extremal self-dual code of length 36 that admits an automorphism of order 3. In addition, it was proved in that if  $C$  is an extremal ternary self-dual code of length 36 then either  $C$  is equivalent to the Pless symmetry code or the full automorphism group of  $C$  is a subgroup of the cyclic group of order 8.

⇒ Symmetric 2-(36, 15, 6) designs with an involution and their ternary codes?

---

<sup>10</sup>W. C. Huffman, On extremal self-dual ternary codes of lengths 28 to 40, *IEEE Trans. Info. Theory* **38** No. 4 (1992), 1395-1400.

<sup>11</sup>S. Eisenbarth, G. Nebe, Self-dual codes over chain rings, *Math. Comput. Sci.* **14** (2020), 443 - 456.

- It is known that every finite group of order  $2^n$  contains a subgroup of order  $2^i$  for every  $i$  in the range  $1 \leq i \leq n$ . By this property, finding all nonisomorphic 2-(36, 15, 6) designs which are invariant under an involution and whose incidence matrix spans a ternary extremal self-dual code, will also give the enumeration of all nonisomorphic 2-(36, 15, 6) designs invariant under a nontrivial subgroup of the cyclic group of order 8 with this property.
- For the construction of 2-(36, 15, 6) designs we use the method for constructing orbit matrices with presumed action of an automorphism group, which are then indexed to construct designs. After constructing 2-(36, 15, 6) designs, we check the 3-rank of their incidence matrices, and if it is equal to 18 we determine the minimum weight of the corresponding ternary code.

Let  $\mathcal{D} = (\mathcal{P}, \mathcal{B}, I)$  be a  $2-(v, k, \lambda)$  design and  $G \leq \text{Aut}(\mathcal{D})$ . We denote the  $G$ -orbits of points by  $\mathcal{P}_1, \dots, \mathcal{P}_m$ ,  $G$ -orbits of blocks by  $\mathcal{B}_1, \dots, \mathcal{B}_n$ , and put  $|\mathcal{P}_i| = \nu_i$ ,  $|\mathcal{B}_j| = \beta_j$ ,  $i = 1, \dots, m$ ,  $j = 1, \dots, n$ .

Denote by  $a_{ij}$  the number of blocks of  $\mathcal{B}_j$  which are incident with a representative of the point orbit  $\mathcal{P}_i$ . The number  $a_{ij}$  does not depend on the choice of a point  $P \in \mathcal{P}_i$ , and the following equalities hold:

$$\sum_{j=1}^n a_{ij} = r, \quad (1)$$

$$\sum_{j=1}^n \frac{\nu_t}{\beta_j} a_{sj} a_{tj} = \lambda \nu_t + \delta_{st}(r - \lambda). \quad (2)$$

## Definition

A  $(m \times n)$ -matrix  $M = (a_{ij})$  with entries satisfying conditions (1) and (2) is called a point orbit matrix for the parameters  $2 - (v, k, \lambda)$  and orbit lengths distributions  $(\nu_1, \dots, \nu_m)$  and  $(\beta_1, \dots, \beta_n)$ .

On extremal ternary self-dual codes of length 36 and related symmetric 2-(36, 15, 6) designs

Motivation - known facts

Hadamard matrices derived from the symmetry code of length 36

Symmetric 2-(36, 15, 6) designs with an involution and their ternary codes

Incidence matrix for the symmetric (7,3,1) design

$$\left( \begin{array}{c|ccc|ccc} 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ \hline 1 & 1 & 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 & 1 \\ \hline 0 & 1 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 0 \end{array} \right)$$

Corresponding orbit matrix for  $Z_3$

$$\begin{array}{c|cc|cc} & & 1 & 3 & 3 \\ \hline 1 & & 0 & 3 & 0 \\ \hline 3 & & 1 & 1 & 1 \\ 3 & & 0 & 1 & 2 \end{array}$$

The first step in the construction is to determine possible orbit lengths distributions. For that we need the following facts

- Suppose that a nonidentity automorphism  $\sigma$  of a symmetric 2-( $v, k, \lambda$ ) design fixes  $f$  points. Then

$$f \leq v - 2(k - \lambda) \quad \text{and} \quad f \leq \left( \frac{\lambda}{k - \sqrt{k - \lambda}} \right) v.$$

Moreover, if equality holds in either inequality,  $\sigma$  must be an involution and every non-fixed block contains exactly  $\lambda$  fixed points.<sup>12</sup>

- Suppose that  $\mathcal{D}$  is a nontrivial symmetric 2-( $v, k, \lambda$ ) design, with an involution  $\sigma$  fixing  $f$  points and blocks. If  $f \neq 0$ , then<sup>13</sup>

$$f \geq \begin{cases} 1 + \frac{k}{\lambda}, & \text{if } k \text{ and } \lambda \text{ are both even,} \\ 1 + \frac{k-1}{\lambda}, & \text{otherwise.} \end{cases}$$

$\Rightarrow$  An involution acting on 2-(36, 15, 6) design could have  $f$  fixed points, where  $f \in \{4, 6, 8, 10, 12, 14, 16, 18\}$ , or acts fixed points freely.

---

<sup>13</sup>E. Lander, *Symmetric Designs: An Algebraic Approach*, Cambridge University Press, 1983.[Proposition 4.23]

- There are 119907 orbit matrices for an involution acting on 2-(36, 15, 6) design without fixed points, but none of the corresponding designs yields no self-dual ternary code.
- Orbit matrices do not exist for  $f \in \{6, 14, 18\}$ .
- The results for the remaining cases are summarized in the following table

Number of fixed points	4	8	10	12	16
Number of orbit matrices	12991	670	56	311	83
Number of designs	884139	498592	186369	3719232	209160
max $d$ in self-dual codes	12	×	×	9	×

## Theorem

- (a) *Up to isomorphism, there exists exactly one symmetric 2-(36, 15, 6) design  $D$  that admits an automorphism of order 2 and its incidence matrix spans an extremal ternary self-dual code of length 36.*
- (b) *The full automorphism group  $G$  of  $D$  is of order 24, and  $G$  is isomorphic to the symmetric group  $S_4$ .*
- (c) *The regular Hadamard matrix associated with  $D$  is equivalent to the Paley-Hadamard matrix of type II.*
- (d) *The ternary code spanned by  $D$  is equivalent to the Pless symmetry code.*

On extremal  
ternary self-dual  
codes of length  
36 and related  
symmetric  
 $2-(36, 15, 6)$   
designs

Motivation -  
known facts

Hadamard  
matrices derived  
from the  
symmetry code of  
length 36

Symmetric  
 $2-(36, 15, 6)$   
designs with an  
involution and  
their ternary  
codes
